(Received 25 September 2021 • Revised 29 November 2021 • Accepted 2 December 2021)

**Abstract**—Inorganic polymer flocculants play an important role in water treatment. The copolymerization of  $\text{Al}^{3+}$  and  $\text{Fe}^{3+}$  in proportion can prepare polyferric aluminum (PFA), which can improve the flocculation performance of polyferric (PFe) on the premise of reducing  $\text{Al}^{3+}$  residue. The effects of  $\text{Al}/\text{Fe}$  and  $\text{OH}^-/\text{Fe}$  on the micromorphology, physicochemical properties and flocculation performance of polyferric aluminum phosphatic sulfate (PFAPS) were studied in this work. The results show that  $\text{Fe}^{3+}$  and  $\text{Al}^{3+}$  form Fe-monomer and Al-monomer by combining with six oxygen atoms from  $\text{H}_2\text{O}$  or anion. And then these monomers form polymers through the bridging of various anions. Although the binding mode is similar, XRD results show that pfaps and PFPS are amorphous. The flocculation performance of PFAPS first increases and then decreases with the increase of  $\text{Al}/\text{Fe}$  and  $\text{OH}^-/\text{Fe}$ .

Keywords: Polymerization Mechanism, Simulated Dye Wastewater, Molecular Dynamics Simulation

## INTRODUCTION

The security of water resources plays a crucial role in the sustainable development of human society, what is the basic resource of promoting economic development and social progress [1]. Environmentally-safe treatment of domestic and industrial wastewater containing pollutants, on the one hand, can avoid polluting more water sources; on the other hand, can also recycle the treated water [2]. Flocculation-coagulation is one of the most widely applied wastewater treatment technologies [3]. With the continuous development of flocculants, flocculation can not only separate suspended solids from water [4], but also play a role in oil removal [5], decolorization [6], phosphorus removal [7], heavy metal removal [8], and organic matter removal [9] of water treatment.

Polyaluminum (PAL) is one of the most frequently used flocculants [10,11]. Compare with metal salts such as  $\text{AlCl}_3$  or  $\text{Al}_2(\text{SO}_4)_3$ , whose morphology distribution of the formed metal ion polymer cannot be controlled due to its rapid hydrolysis in the wastewater [12], PAL has better flocculant performance. PAL contain many positively charged polymers. They can destabilize the colloidal pollutants by electric neutralization and compressing electric double layer, and form flocs which are easy to precipitate by adsorption bridging and net sweeping [13].

However, Al can cause oxidative stress and inflammation in human body, damage multiple organs [14], destroy intestinal barrier [15] and brain nerve cells [16]. In 1989, the World Health Organization (WHO) and the Food and Agriculture Organization (FAO) of the United Nations officially listed Al as a food pollutant. While Fe is basically harmless to human body, and Ployferric (PFe) has the advantages of wide raw material sources, low production cost,

non-toxic, wide temperature and pH value application range [17-19], what is an ideal substitute for PAL. However, the flocculation performance and stability of PFe are weaker than of PAL. Composite flocculant polyferric aluminum (PFA) is formed by copolymerization of  $\text{Al}^{3+}$  and  $\text{Fe}^{3+}$  in proportion, which can reduce the residual of Al and improve the flocculation performance of PFe. Although PFA has been reported that it has good flocculation effect on turbidity and COD [20-23], it also has a broader application prospect in the treatment of chemical engineering, paper, dye, mining and other industry wastewater and a certain research value in its polymerization mechanism. The understanding of its polymerization mechanism is not only conducive to the determination of its optimal preparation conditions, but also conducive to its utilization in wastewater treatment.

In this paper, polyferric aluminum phosphatic sulfate (PFAPS) was prepared by copolymerization of  $\text{Fe}_2(\text{SO}_4)_3$  and  $\text{Al}_2(\text{SO}_4)_3$  with  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  and  $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$  as raw materials,  $\text{H}_2\text{O}_2$  as oxidant and  $\text{H}_3\text{PO}_4$  as stabilizer. The effects of  $\text{Al}/\text{Fe}$  and  $\text{OH}^-/\text{Fe}$  on the polymerization and flocculation performance of PFAPS were studied. The crystal structure and chemical bond of PFAPS were characterized by XRD and FTIR. And the polymerization mechanism of PFAPS was studied by molecular dynamics (MD) simulation.

## EXPERIMENTAL

### 1. MD Simulation Details

In this work, GROMACS 2018.4 software package [24] was used to simulate the PFPS, PFAPS<sub>3</sub> and PFAPS<sub>8</sub>. According to the molar ratio of ions in the actual preparation system, considering the local aggregation of  $\text{OH}^-$  around  $\text{Fe}^{3+}$  and  $\text{Al}^{3+}$ , the particle number are determined. There are 2000  $\text{H}_2\text{O}$ , 48  $\text{OH}^-$ , 24  $\text{SO}_4^{2-}$ , 16  $\text{PO}_4^{3-}$  and 48  $\text{Fe}^{3+}$  in PFPS system. There are 2000  $\text{H}_2\text{O}$ , 48  $\text{OH}^-$ , 33  $\text{SO}_4^{2-}$ , 18  $\text{PO}_4^{3-}$ , 48  $\text{Fe}^{3+}$  and 8  $\text{Al}^{3+}$  in PFAPS<sub>3</sub> system. There are 2000  $\text{H}_2\text{O}$ , 56  $\text{OH}^-$ , 28  $\text{SO}_4^{2-}$ , 18  $\text{PO}_4^{3-}$ , 48  $\text{Fe}^{3+}$  and 8  $\text{Al}^{3+}$  in PFAPS<sub>8</sub> system.

The initial structures of H<sub>2</sub>O, OH<sup>-</sup>, SO<sub>4</sub><sup>2-</sup> and PO<sub>4</sub><sup>3-</sup> were constructed by Gaussview6 and optimized by Gaussian 09 using B3LYP theory and 6-311G+(3df2) basis set. The restrained electrostatic potential (RESP) of the atom was calculated by Multiwfn 3.8 [25]. The force field (GAFF) in AMBER [26] was used to obtain the force field parameters of each particle except Fe<sup>3+</sup> and Al<sup>3+</sup>. The force fields of Fe<sup>3+</sup> and Al<sup>3+</sup> were obtained from reference [27]. TIP3P water model was used in the simulation.

Packmol [28] was used to arrange the particles of the simulation systems in 7×7×7 nm simulation box with periodic boundary, and the distance between the molecules is more than 0.2 nm. The energy minimization method was used to optimize the simulation box, and the maximum force between atoms was less than 500 kJ/(mol·nm). At a constant temperature (298.15 K) and a constant pressure (1 bar), V-rescale and Parrinello Rahman methods were used to control the temperature and pressure, respectively. The NVT ensemble of 100 ps was carried out with step size of 2 fs. After the temperature equilibrium was reached, the NPT ensemble of 100 ps was carried out with step size of 2 fs. Then, under isothermal and isobaric conditions, the MD simulation with step size of 0.8 fs was carried out for 50 ns to obtain the final simulation results.

## 2. Materials

FeSO<sub>4</sub>·7H<sub>2</sub>O (Tianjin kernel Co., China), H<sub>2</sub>O<sub>2</sub> (Tianjin Chemical Reagent Supply and Marketing Co., China), Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·18H<sub>2</sub>O (Tianjin Damao Co., China), H<sub>2</sub>SO<sub>4</sub> (Tianjin Damao Co., China) and Na<sub>2</sub>CO<sub>3</sub> (Tianjin Jiangtian Co., China) used in this study are analytical grade reagents. Except for simulated wastewater, the solvents used are deionized water (the conductivity 2.55 μS/cm, Tianjin Yongqingyuan Co., China).

## 3. Preparation of PFPS and PFAPS

0.05 mol FeSO<sub>4</sub>·7H<sub>2</sub>O and 0.005 mol H<sub>2</sub>SO<sub>4</sub> were added in 10 ml deionized water, and then they were stirred to mix evenly in a water bath at 30 °C. Under stirring condition, 0.04 mol H<sub>2</sub>O<sub>2</sub> was dripped into solution for oxidation. After 30 min, it was placed at room temperature. 0.005 mol H<sub>3</sub>PO<sub>4</sub> was added and stirred for 10 min. Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·18H<sub>2</sub>O was added according to different Al/Fe ratios and stirred for 10 min. And then liquid PFAPS samples with different Al/Fe ratios were obtained by aging in water bath at 50 °C for 2 h. To obtain PFAPS samples with different OH<sup>-</sup>/Fe, after adding Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·18H<sub>2</sub>O according to Al/Fe=0.15, Na<sub>2</sub>CO<sub>3</sub> was added according to different OH<sup>-</sup>/Fe and stirred for 10 min. PFAPS sam-

ples with different OH<sup>-</sup>/Fe were obtained by aging in 50 °C water bath for 2 h. The specific preparation parameters are shown in Table 1.

## 4. Analytical Methods for PFAPS

The content of Fe<sup>2+</sup> ([Fe<sup>2+</sup>]), The content of total Fe ([TFe]) and OH<sup>-</sup>/(Al+Fe) of PFAPS were determined according to GB/T14591-2016 *Water treatment chemicals—Poly ferric sulfate* [29]. According to the method described in the literature [30], Ferron-Fe timed spectroscopy method was used to determine the distribution of Fe(III) species. According to the different reaction time with Ferron, Fe(III) can be divided into Fe<sub>a</sub>, Fe<sub>b</sub> and Fe<sub>c</sub> species. Fe<sub>a</sub> is the component that reacts with Ferron in 30 seconds, what is considered to be Fe<sup>3+</sup> and Fe-monomer, Fe<sub>b</sub> is the component that reacts with Ferron in 30 seconds to 24 hours, what is considered to be Fe-polymer. And Fe<sub>c</sub> is the component that still does not react with Ferron in 24 hours, what is considered to be uncharged precipitate. The conductivity of the liquid PFAPS samples was measured by conductivity meter (DDSJ-318, Shanghai INESA Scientific Instrument, China). Some liquid samples were dried at 70 °C for 24 h to prepare solid PFAPS for XRD (MiniFlex600, Rigaku, Japan, scanning rate: 4°/min, radiation range: 10°-80° (2θ) and FTIR (Nicolet 6700, Thermo Fisher Scientific, USA, spectral range: 4,000-400 cm<sup>-1</sup>) characterizations.

## 5. Simulated Dye Wastewater

Disperse yellow (DY, Zhejiang Shanyu Dyestuff Co., China) and reactive turquoise blue (RTB, Shanghai Wande Co., China) were used for the flocculation experiments of PFAPS. DY is a hydrophobic dye, and RTB is an anionic hydrophilic dye. Tap water was used to prepare these dyes into 0.1 g/L simulated dye wastewater for assessing the flocculation performance of PFAPS. The absorbance at 445 nm and 618 nm is proportional to the concentration of DY and RTB simulated dye wastewater respectively. And the absorbance of 0.1 g/L DY and RTB simulated dye wastewater are 1.0165±0.027 Abs and 1.4611±0.019 Abs respectively.

## 6. Flocculation Experiments

Flocculation experiment was carried out at 25 °C on the coagulation test mixer (MY3000-6M, Wuhan Meiyu Co. Ltd., China). In each experiment, 200 ml dye solution in a 300 ml beaker was added liquid PFAPS with a certain dosage and stirred at 250 rpm for 1 min, then at 35 rpm for 15 min, and the flocculated dye solution stood for 20 min. The above supernatant was sampled for measuring the pH value by a pH meter (PHS-3C, Shanghai Youke Instrument Co., China, Measuring range: 0-14.00 pH, Basic error: ±0.02 pH). The supernatant absorbance was determined by an ultraviolet visible spectrophotometer (L6S, Shanghai Precision Instrument Co., China, Wavelength range: 190-1,100 nm, Absorbance range: -0.301-4.000 A, Maximum allowable error: ±0.3%), and the decolorization efficiency of the dye solution was calculated according to Eq. (1). The residual PO<sub>4</sub><sup>3-</sup> and Al<sup>3+</sup> of DY and RTB supernatant treated by PFAPS<sub>1-9</sub> in experimental maximum dose are measured by multi-parameter Water Survey Instrument (HI 83200, Hanna Instruments, Inc., Italy).

$$\text{Decolorization efficiency (\%)} = \frac{A_0 - A_1}{A_0} \times 100\% \quad (1)$$

## RESULTS AND DISCUSSION

### 1. MD Simulation Results

The molecular dynamics (MD) simulation results of PFPS, PFAPS<sub>3</sub> and PFAPS<sub>8</sub> are shown in Fig. 1, and the results of MD simulation without H<sub>2</sub>O which is not bound with Fe<sup>3+</sup> are shown in Fig. 2.

As shown in Fig. 2, the surrounding of Fe<sup>3+</sup> and Al<sup>3+</sup> will be regularly arranged with six oxygen atoms from the same or different particles to form Fe-monomer and Al-monomer. This is because Fe<sup>3+</sup> and Al<sup>3+</sup> both have 1 s orbital, 3 p orbitals and 2 d orbitals hybridized into sp<sup>3</sup>d<sup>2</sup> orbitals which contain lone pair electrons of the surrounding six oxygen atoms to form ligands. These Fe-monomers and Al-monomers are the raw material of polynuclear complex ion (polymers) production in polymerization process of Fe based and Al based inorganic polymer flocculants [31-34]. Different kinds of Fe-monomers and Al-monomers in the three systems are shown in Fig. S1 and Fig. S2, respectively. There are 3 [Fe(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> (Fig. S1(a)), 15 [Fe(H<sub>2</sub>O)<sub>5</sub>OH]<sup>2+</sup> (Fig. S1(b)), 4 Fe(H<sub>2</sub>O)<sub>5</sub>SO<sub>4</sub><sup>+</sup> (Fig. S1(c)), 4 Fe(H<sub>2</sub>O)<sub>5</sub>PO<sub>4</sub> (Fig. S1(d)), 1 [Fe(H<sub>2</sub>O)<sub>4</sub>

(OH)<sub>2</sub>]<sup>+</sup> (Fig. S1(e)), 4 Fe(H<sub>2</sub>O)<sub>4</sub>OHSO<sub>4</sub> (Fig. S1(f)), 2 [Fe(H<sub>2</sub>O)<sub>4</sub>OHPO<sub>4</sub>]<sup>-</sup> (Fig. S1(g)), 2 Fe(H<sub>2</sub>O)<sub>4</sub>PO<sub>4</sub> (Fig. S1(j)), 2 Fe(H<sub>2</sub>O)<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> (Fig. S1(k)), 1 [Fe(H<sub>2</sub>O)<sub>3</sub>PO<sub>4</sub>SO<sub>4</sub>]<sup>2-</sup> (Fig. S1(m)), 2 [Fe(H<sub>2</sub>O)<sub>3</sub>PO<sub>4</sub>SO<sub>4</sub>]<sup>2-</sup> (Fig. S1(n)), 4 Fe(H<sub>2</sub>O)<sub>3</sub>OHSO<sub>4</sub> (Fig. S1(p)), 1 [Fe(H<sub>2</sub>O)<sub>3</sub>OHPO<sub>4</sub>]<sup>-</sup> (Fig. S1(q)), 1 [FeH<sub>2</sub>O(SO<sub>4</sub>)<sub>2</sub>PO<sub>4</sub>]<sup>4-</sup> (Fig. S1(s)), 1 [Fe(H<sub>2</sub>O)<sub>2</sub>(PO<sub>4</sub>)<sub>2</sub>]<sup>3-</sup> (Fig. S1(u)) and 1 [Fe(H<sub>2</sub>O)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>PO<sub>4</sub>]<sup>4-</sup> (Fig. S1(v)) in the PFPS simulation system; There are 2 [Fe(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> (Fig. S1(a)), 18 [Fe(H<sub>2</sub>O)<sub>5</sub>OH]<sup>2+</sup> (Fig. S1(b)), 5 [Fe(H<sub>2</sub>O)<sub>5</sub>SO<sub>4</sub>]<sup>+</sup> (Fig. S1(c)), 8 Fe(H<sub>2</sub>O)<sub>5</sub>PO<sub>4</sub> (Fig. S1(d)), 2 [Fe(H<sub>2</sub>O)<sub>4</sub>(OH)<sub>2</sub>]<sup>+</sup> (Fig. S1(e)), 4 [Fe(H<sub>2</sub>O)<sub>4</sub>OHPO<sub>4</sub>]<sup>-</sup> (Fig. S1(g)), 1 [Fe(H<sub>2</sub>O)<sub>4</sub>(PO<sub>4</sub>)<sub>2</sub>]<sup>3-</sup> (Fig. S1(h)), 1 [Fe(H<sub>2</sub>O)<sub>4</sub>SO<sub>4</sub>PO<sub>4</sub>]<sup>2-</sup> (Fig. S1(i)), 2 Fe(H<sub>2</sub>O)<sub>4</sub>PO<sub>4</sub> (Fig. S1(j)), 1 [Fe(H<sub>2</sub>O)<sub>3</sub>PO<sub>4</sub>SO<sub>4</sub>]<sup>2-</sup> (Fig. S1(n)), 1 Fe(H<sub>2</sub>O)<sub>3</sub>OHSO<sub>4</sub> (Fig. S1(p)), 2 [Fe(H<sub>2</sub>O)<sub>3</sub>OHPO<sub>4</sub>]<sup>-</sup> (Fig. S1(q)), 1 [FeH<sub>2</sub>O(SO<sub>4</sub>)<sub>2</sub>PO<sub>4</sub>]<sup>3-</sup> (Fig. S1(t)), 4 [Al(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> (Fig. S2(a)), 1 [Al(H<sub>2</sub>O)<sub>5</sub>OH]<sup>2+</sup> (Fig. S2(b)), 2 Al(H<sub>2</sub>O)<sub>4</sub>PO<sub>4</sub> (Fig. S2(c)) and 1 [AlH<sub>2</sub>O(SO<sub>4</sub>)<sub>2</sub>]<sup>3-</sup> (Fig. S2(h)) in the PFAPS<sub>3</sub> simulation system; There are 4 [Fe(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> (Fig. S1(a)), 16 [Fe(H<sub>2</sub>O)<sub>5</sub>OH]<sup>2+</sup> (Fig. S1(b)), 5 [Fe(H<sub>2</sub>O)<sub>5</sub>SO<sub>4</sub>]<sup>+</sup> (Fig. S1(c)), 1 Fe(H<sub>2</sub>O)<sub>5</sub>PO<sub>4</sub> (Fig. S1(d)), 5 [Fe(H<sub>2</sub>O)<sub>4</sub>(OH)<sub>2</sub>]<sup>+</sup> (Fig. S1(e)), 1 Fe(H<sub>2</sub>O)<sub>4</sub>OHSO<sub>4</sub> (Fig. S1(f)), 1 [Fe(H<sub>2</sub>O)<sub>4</sub>OHPO<sub>4</sub>]<sup>-</sup> (Fig. S1(g)), 1 Fe(H<sub>2</sub>O)<sub>4</sub>PO<sub>4</sub>SO<sub>4</sub> (Fig. S1(i)), 4 Fe(H<sub>2</sub>O)<sub>4</sub>PO<sub>4</sub> (Fig. S1(j)), 1 Fe(H<sub>2</sub>O)<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> (Fig. S1(k)), 1 [Fe(H<sub>2</sub>O)<sub>3</sub>PO<sub>4</sub>SO<sub>4</sub>]<sup>2-</sup> (Fig. S1(m)), 1 [Fe(H<sub>2</sub>O)<sub>3</sub>

Fig. 1. The MD simulation results of the simulation systems of PFPS (a) PFAPS<sub>3</sub> (b) and PFAPS<sub>8</sub> (c) (Red: O, White: H, Yellow: S, Blue: Fe, Orange: P, Green: Al).

Fig. 2. The MD simulation results without H<sub>2</sub>O which not bound with Fe<sup>3+</sup> of PFPS (a) PFAPS<sub>3</sub> (b) and PFAPS<sub>8</sub> (c) simulation systems (Red: O, White: H, Yellow: S, Blue: Fe, Orange: P, Green: Al).

$\text{PO}_4\text{SO}_4\text{]}^{2-}$  (Fig. S1(n)), 2  $\text{Fe}(\text{H}_2\text{O})_3\text{OH}\text{SO}_4$  (Fig. S1(p)), 1  $[\text{Fe}(\text{H}_2\text{O})_3\text{OH}\text{PO}_4]^-$  (Fig. S1(q)), 1  $[\text{Fe}(\text{H}_2\text{O})_2(\text{OH})_2\text{PO}_4]^{2-}$  (Fig. S1(r)), 1  $[\text{Fe}(\text{H}_2\text{O})_2(\text{SO}_4)_2\text{PO}_4]^{4+}$  (Fig. S1(w)), 1  $[\text{FeH}_2\text{OSO}_4(\text{PO}_4)_2]^{5-}$  (Fig. S1(x)), 1  $[\text{Fe}(\text{H}_2\text{O})_2\text{OH}(\text{PO}_4)_2]^{4+}$  (Fig. S1(y)), 2  $[\text{Al}(\text{H}_2\text{O})_6]^{3+}$  (Fig. S2(a)), 1  $\text{Al}(\text{H}_2\text{O})_4\text{PO}_4$  (Fig. S2(c)), 1  $[\text{Al}(\text{H}_2\text{O})_3\text{OH}\text{PO}_4]^-$  (Fig. S2(d)), 1  $\text{Al}(\text{H}_2\text{O})_4\text{OH}\text{SO}_4$  (Fig. S2(e)), 1  $[\text{Al}(\text{H}_2\text{O})_3\text{PO}_4\text{SO}_4]^{2-}$  (Fig. S2(f)) and 2  $[\text{Al}(\text{H}_2\text{O})_3\text{SO}_4]^+$  (Fig. S2(g)) in the PFAPS<sub>8</sub> simulation system.

According to the MD simulation results shown in Fig. 2, compared the results of PFPS and PFAPS<sub>3</sub>, the addition of  $\text{Al}^{3+}$  will affect the number of anions bound with  $\text{Fe}^{3+}$ , and then affect the polymerization of Fe-polymer. Specifically, the number of  $\text{PO}_4^{3-}$  bound with  $\text{Fe}^{3+}$  decreases from 15 to 12, while the number of  $\text{OH}^-$  bound with  $\text{Fe}^{3+}$  increases from 28 to 31. It indicates that the addition of  $\text{Al}^{3+}$  will compete with  $\text{Fe}^{3+}$  for  $\text{PO}_4^{3-}$ , which is adverse to the substitution of  $\text{PO}_4^{3-}$  for  $\text{OH}^-$  in  $\text{Fe}^{3+}$  polymerization and promotes the hydrolysis of  $\text{Fe}^{3+}$ . Comparing the results of PFAPS<sub>3</sub> and PFAPS<sub>8</sub>, the addition of  $\text{OH}^-$  can promote the polymerization of both  $\text{Al}^{3+}$  and  $\text{Fe}^{3+}$ . Specifically, the number of  $\text{OH}^-$  bound with  $\text{Fe}^{3+}$  increases from 31 to 35, and the number of  $\text{OH}^-$  bound with  $\text{Al}^{3+}$  increases from 1 to 4.

Fe-monomers and Al-monomers form polymers through the bridging of various anions [31-34], such as  $\text{OH}^-$ ,  $\text{PO}_4^{3-}$ , and  $\text{SO}_4^{2-}$ . According to the MD simulation results shown in Fig. 2, the metal ion monomers formed with  $\text{Al}^{3+}$  and  $\text{Fe}^{3+}$  as the center will form micro polymers by the bridging of anions in three forms: (1) different monomers share the same anion, (2) The mutual attraction between different monomers, and (3) different monomers are attracted by the same anion, as shown in Fig. S3. In the three simulation systems of PFPS, PFAPS<sub>3</sub> and PFAPS<sub>8</sub>, the micro-polymer formed in mode (1) is shown in Fig. S3(a), (b) and (c); The micro-polymer formed in mode (2) is shown in Fig. S3(d), (e), (f); The micro-polymer formed in mode (3) is shown in Fig. S3(g), (h), (j). These micro polymers will continue to form larger polymers

through the latter two ways.

## 2. Characterization of PFAPS

### 2-1. Physicochemical Properties of PFAPS

#### (1) Effect of Al/Fe

The physicochemical properties of PFAPS samples with different Al/Fe ratios are shown in Table 2. The results show that with the increase of Al/Fe, the density of flocculant samples increases, the [TFe] and  $\text{OH}^-/3(\text{Fe}+\text{Al})$  of PFAPS samples decreases, and its pH value changes little. The conductivity of PFAPS<sub>1</sub>, PFAPS<sub>2</sub> and PFAPS<sub>3</sub> are similar, lightly higher than that of PFPS, and significantly lower than that of PFAPS<sub>4</sub>. It shows that when  $\text{Al/Fe} > 0.15$ , the newly added  $\text{Al}^{3+}$  no longer combines with the existing charged particles, but forms new charged particles, which makes the conductivity of the sample increase obviously. The  $[\text{Fe}^{2+}]$  of PFPS samples is lower than 0.01%, which indicates that  $\text{Fe}^{2+}$  is completely oxidized during the preparation process. The results of Fe(III) species distribution show that compared with PFPS, the content of  $\text{Fe}_a$  increases, the content of  $\text{Fe}_c$  decreases, while the content of  $\text{Fe}_b$  changes little in PFAPS<sub>1</sub>. This is because the addition of  $\text{Al}^{3+}$  will compete with  $\text{Fe}^{3+}$  for  $\text{OH}^-$ , hinder the combination of  $\text{Fe}^{3+}$  and  $\text{OH}^-$ , and affect the polymerization of Fe polymer, resulting in the increase of  $\text{Fe}_a$  and the decrease of  $\text{Fe}_c$ . Then, with the increase of Al/Fe, the content of  $\text{Fe}_a$  changes little, the content of  $\text{Fe}_b$  slightly decreases and the content of  $\text{Fe}_c$  slightly increases. This is because that the addition of  $\text{Al}^{3+}$  will compete with  $\text{Fe}^{3+}$  for  $\text{PO}_4^{3-}$ , which is adverse to the substitution of  $\text{PO}_4^{3-}$  for  $\text{OH}^-$  in the polymerization process of  $\text{Fe}^{3+}$ , resulting in the reduction of the stability of Fe-polymer and the improvement of the content of uncharged precipitation.

#### (2) Effect of $\text{OH}^-/\text{Fe}$

The physicochemical properties of PFAPS samples with different  $\text{OH}^-/\text{Fe}$  are shown in Table 3. The results show that with the increase of  $\text{OH}^-/\text{Fe}$ , the density and [TFe] of PFPS samples decrease,

**Table 2. Characteristics of flocculant samples with different Al/Fe ratios**

Fig. 3. XRD results of the powder samples of PFPS, PFAPS<sub>3</sub>, PFAPS<sub>5</sub>, and PFAPS<sub>9</sub>.

while the pH value, conductivity and  $\text{OH}^-/3(\text{Fe}+\text{Al})$  increase. The  $[\text{Fe}^{2+}]$  of PFPS samples is lower than 0.01%, which indicates that  $\text{Fe}^{2+}$  is completely oxidized during the preparation process. The results of Fe(III) species distribution show that compared with PFAPS<sub>3</sub>, the content of  $\text{Fe}_a$  decreases, the content of  $\text{Fe}_b$  and  $\text{Fe}_c$  increase in PFAPS<sub>5</sub>. Then, with the increase of  $\text{OH}^-/\text{Fe}$ , the content of  $\text{Fe}_a$  changes little, the content of  $\text{Fe}_b$  slightly decreases and the content of  $\text{Fe}_c$  slightly increases. This is due to the reaction of  $\text{Na}_2\text{CO}_3$  with  $\text{H}^+$  in the preparation solution, which increases the concentration of  $\text{OH}^-$ , and promotes the polymerization of Fe polymer. When  $\text{OH}^-/\text{Fe} < 0.025$ ,  $\text{Fe}_a$  can be promoted to polymerize into  $\text{Fe}_b$ , and then addition more  $\text{Na}_2\text{CO}_3$  can promote  $\text{Fe}_b$  to polymerize into  $\text{Fe}_c$ . At the same time, the increase of  $\text{OH}^-/\text{Fe}$  can

also promote the polymerization of Al-polymer.

## 2-2. XRD Results

Liquid samples of PFPS, PFAPS<sub>3</sub>, PFAPS<sub>5</sub> and PFAPS<sub>9</sub> were dried at 70 °C for 24 h and then ground to obtain solid powder samples which were characterized by XRD. The results are shown in Fig. 3, which indicate that PFPS, PFAPS<sub>3</sub>, PFAPS<sub>5</sub> and PFAPS<sub>9</sub> are amorphous structure. The results show that the addition of  $\text{Al}^{3+}$  does not produce crystal PFAPS. Although the increase of  $\text{OH}^-/\text{Fe}$  can promote the polymerization of PFAPS and improve its crystallinity, it is still unable to form a three-dimensional periodic crystal structure. These results are similar to the XRD results of inorganic polymer flocculants in the literature [13].

## 2-3. FTIR Results

Liquid samples of PFPS, PFAPS<sub>3</sub> and PFAPS<sub>9</sub> were dried at 70 °C for 24 h and then ground to obtain solid powder samples which were characterized by FTIR. The results are shown in Fig. 4. The broad absorption peak at 3,100-3,400  $\text{cm}^{-1}$  corresponds to the stretching vibration of -OH [35], the absorption peak near 3,180  $\text{cm}^{-1}$  corresponds to the OH group bound with Fe [36], and the absorption peak near 3,370  $\text{cm}^{-1}$  corresponds to the OH group bound with Al [37]. The comparison shows that the addition of  $\text{Al}^{3+}$  makes Al-OH appear in PFAPS<sub>3</sub>, and the increase of  $\text{OH}^-/\text{Fe}$  enhances the existence of Al-OH in PFAPS<sub>9</sub>. Three samples all have absorption peaks near 1,645  $\text{cm}^{-1}$ , corresponding to the bending vibration of H-O-H [38], indicating the presence of bound water in the samples. The absorption peak near 1,100  $\text{cm}^{-1}$  corresponds to Fe-OH-Fe [39] or Al-OH-Al group [33], while the absorption peak near 1,035  $\text{cm}^{-1}$  corresponds to Fe-O-P [40]. It is found that both PFPS and PFAPS<sub>9</sub> have absorption peaks near 1,100  $\text{cm}^{-1}$  and 1,035  $\text{cm}^{-1}$ , while PFAPS<sub>3</sub> only has absorption peak near 1,100  $\text{cm}^{-1}$ . This is because that the addition of  $\text{Al}^{3+}$  make Al-OH-Al which enhances the absorption peaks near 1,100  $\text{cm}^{-1}$  produce in the sample. While the competition between  $\text{Al}^{3+}$  and  $\text{Fe}^{3+}$  for  $\text{PO}_4^{3-}$  weakens the absorption peak near 1,035  $\text{cm}^{-1}$ ; The increase of  $\text{OH}^-$  concentration in PFAPS<sub>9</sub> not only increases the Al-OH-Al group, but also weakens the ability of  $\text{Al}^{3+}$  competing with  $\text{Fe}^{3+}$  for  $\text{PO}_4^{3-}$ . There is an absorption peak near 595  $\text{cm}^{-1}$  in the three samples, which corresponds to the bending vibration of Fe-OH [36]. PFPS

Fig. 4. FTIR results of the powder samples of PFPS, PFAPS<sub>3</sub>, and PFAPS<sub>9</sub>.

has an absorption peak near  $452.6\text{ cm}^{-1}$ , which corresponds to the Fe-O group, while PFAPS<sub>2</sub> and PFAPS<sub>3</sub> have absorption peaks at  $483.3\text{ cm}^{-1}$  and  $521.7\text{ cm}^{-1}$ , respectively, which can be attributed to the superposition of the absorption peaks of Fe-O and Al-OH [36]. In conclusion, there are chemical bonds formed by the combination between  $\text{Al}^{3+}$ ,  $\text{Fe}^{3+}$  and  $\text{H}_2\text{O}$ ,  $\text{OH}^-$ ,  $\text{PO}_4^{3-}$  in PFAPS, which is consistent with the MD results.

### 3. Flocculation Performance of PFAPS

#### 3-1. Effect of Al/Fe

The decolorization rate of RTB and DY wastewater treated by PFAPS samples with different ratios of Al/Fe and the pH value of supernatant after treatment are shown in Fig. 5. With the increase of Al/Fe, the decolorization rate of PFAPS first increases and then decreases. And the highest decolorization rate is got by PFAPS<sub>3</sub> with Al/Fe=0.15. Specifically, for RTB, when the dosage is 32 mg/L, the decolorization rate raises from 85.2% of PFPS to 96.8% of PFAPS<sub>3</sub> with Al/Fe=0.15, then reduce to 95.8% of FPSiS<sub>4</sub> with Al/Fe=0.2; for the DY wastewater, when the dosage is 17.5 mg/L, the decolorization rate raises from 86.2% of PFPS to 97.6% of PFAPS<sub>3</sub> with Al/Fe=0.15, then reduce to 96.0% of FPSiS<sub>4</sub> with Al/Fe=0.2. This is because that the increase of Al/Fe can improve the num-

ber of positively charged metal polymer in flocculant samples, which enhances their ability of compressing electric double layer and electric neutralization, resulting in the improvement of the flocculation performance. However, the added  $\text{Al}^{3+}$  will compete with  $\text{Fe}^{3+}$  for  $\text{PO}_4^{3-}$  and  $\text{OH}^-$ . On the one hand, the decrease of  $\text{OH}^-/3(\text{Fe}+\text{Al})$  can reduce the polymerization of Fe-polymer, which is not conducive to their ability of adsorption bridging and net sweeping; on the other hand, weakening the enhancement of  $\text{PO}_4^{3-}$  on the stability of the Fe-polymer will increase the content of uncharged precipitates. These two aspects have an adverse effect on the flocculation performance of PFAPS. The above factors lead to that the flocculation effect of PFAPS increases first and then decreases, with the increase of Al/Fe.

For the RTB wastewater, the pH value of the supernatant changes little first and then decreases significantly with the addition of flocculant. This is because when the dosage of flocculant is small, most of the polymers in the sample are combined with the pollutants in the simulated wastewater. When the dosage of flocculant is large, after combining with the pollutants, the remaining polymer can be hydrolyzed in the simulation wastewater. Moreover, the increase of Al/Fe improves the concentration of metal polymer in

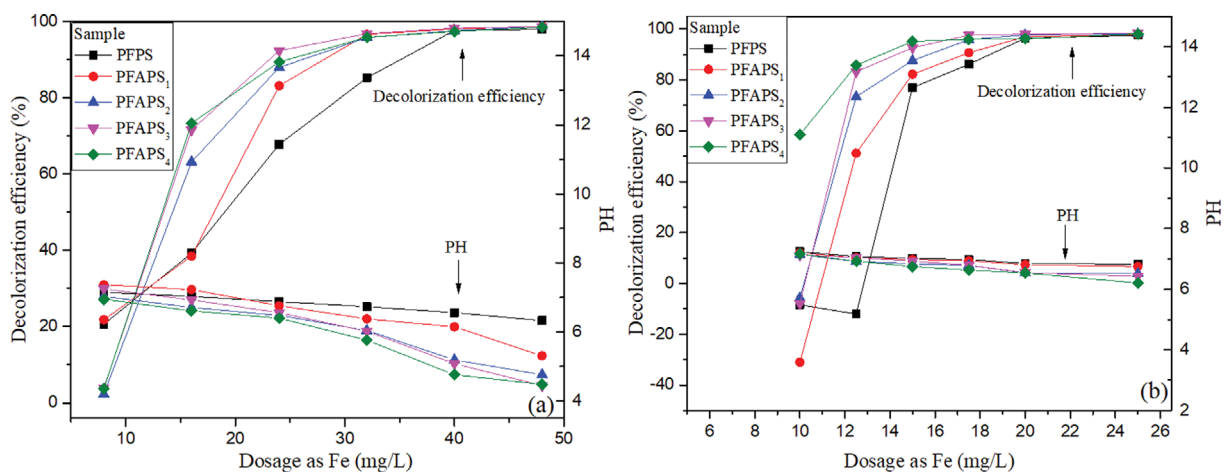

Fig. 5. Decolorization efficiency of PFAPS samples with different Al/Fe ratios on RTB (a) and DY (b) wastewater and pH of their supernatant.

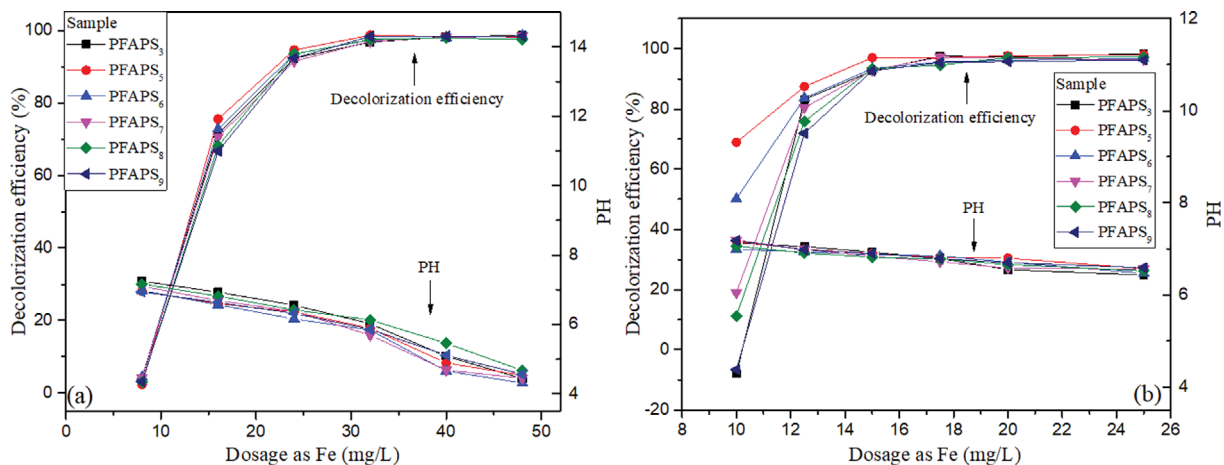

Fig. 6. Decolorization efficiency of PFAPS samples with different  $\text{OH}^-/\text{Fe}$  on RTB (a) and DY (b) wastewater and pH of their supernatant.

| PFAPS <sub>7</sub> | 1.9                          | 0.5                                  | 0.16     | 0.05                        | 0.7                                  | 0.22     |
| PFAPS <sub>8</sub> | 1.72                         | 0.8                                  | 0.25     | 0.04                        | 0.6                                  | 0.19     |
| PFAPS <sub>9</sub> | 0.15                         | 0.8                                  | 0.25     | 0.04                        | 0.5                                  | 0.16     |

the sample which improves their hydrolysis ability. So that the increase of Al/Fe expands the decrease of pH increases. For the DY wastewater, the pH value of supernatant changes little with the dosage of flocculant, which can be due to adsorption of negatively charged DY and its flocs on positively charged polymers.

### 3-2. Effect of OH<sup>-</sup>/Fe

The decolorization rate of RTB and DY wastewater treated by PFAPS samples with different ratios of OH<sup>-</sup>/Fe and the pH value of supernatant after treatment are shown in Fig. 6. With the increase of OH<sup>-</sup>/Fe, the decolorization rate of PFAPS increases firstly and then decreases. And the highest decolorization rate is got by PFAPS<sub>5</sub> with OH<sup>-</sup>/Fe=0.025. Specifically, for the RTB wastewater, when the dosage is 16 mg/L, the decolorization rate raises from 71.5% of PFAPS<sub>3</sub> with OH<sup>-</sup>/Fe=0 to 75.6% of PFAPS<sub>5</sub> with OH<sup>-</sup>/Fe=0.025, then reduce to 66.7% of FPSiS<sub>3</sub> with OH<sup>-</sup>/Fe=0.3; for the DY wastewater, when the dosage is 12.5 mg/L, the decolorization rate raises from 83.2% of PFAPS<sub>3</sub> with OH<sup>-</sup>/Fe=0 to 87.5% of PFAPS<sub>3</sub> with OH<sup>-</sup>/Fe=0.025, then reduce to 71.9% of FPSiS<sub>3</sub> with OH<sup>-</sup>/Fe=0.3. This is because that the increase of OH<sup>-</sup>/Fe improve the active component Fe<sub>b</sub> in PFAPS samples firstly, then further increase of OH<sup>-</sup>/Fe will make Fe<sub>b</sub> turn into Fe<sub>c</sub> which has limited flocculation. The polymerization of Al-polymer is also promoted by the increase of OH<sup>-</sup>/Fe. Because of the excellent stability of Al polymer, its flocculation ability is maintained or even improved. However, it cannot change the trend of flocculation effect decreasing.

For the RTB wastewater, the pH value of supernatant still changes little firstly and then decreases significantly with the increase of flocculant dosage. For the DY wastewater, the pH of the supernatant also changes little with the amount of flocculant.

### 4. Residual PO<sub>4</sub><sup>3-</sup> and Al<sup>3+</sup> in Supernatant

The residual PO<sub>4</sub><sup>3-</sup> and Al<sup>3+</sup> of DY and RTB simulated dye wastewater supernatant treated by PFAPS<sub>1-9</sub> in experimental maximum dose are shown in Table 4. The results show that concentration of Al<sup>3+</sup> and PO<sub>4</sub><sup>3-</sup> in all supernatants can meet the emission standard [41,42].

## CONCLUSION

MD simulation results show Fe<sup>3+</sup> and Al<sup>3+</sup> form Fe-monomer and Al-monomer by combining with six oxygen atoms from H<sub>2</sub>O or anion, which is consistent with FTIR results. And then these mono-

mers form polymers through the bridging of various anions. Although the binding mode is similar, XRD results show that PFAPS and PFPS are amorphous. Although the addition of Al<sup>3+</sup> can increase the number of positively charged metal polymer in PFAPS, it will also compete with Fe<sup>3+</sup> for OH<sup>-</sup> and PO<sub>4</sub><sup>3-</sup>, which affect the polymerization and stability of Fe polymer negatively, resulting in the flocculation performance of PFAPS increases first and then decreases slightly with the increase of Al/Fe. A suitable increase of OH<sup>-</sup>/Fe can promote the formation of active components Fe<sub>b</sub>. While the continuous increase of OH<sup>-</sup>/Fe can make Fe<sub>b</sub> turn into Fe<sub>c</sub> which has limited flocculation. The increase of OH<sup>-</sup>/Fe can also promote the polymerization of Al-polymer. Due to the excellent stability of Al-polymer, its flocculation ability is maintained or even improved. However, it cannot change the trend of flocculation effect decreasing.

## ACKNOWLEDGEMENT

This work is funded by The National Key Research and Development Program of China (Project No. 2017YFC0210203-4).

## SUPPORTING INFORMATION

Additional information as noted in the text. This information is available via the Internet at <http://www.springer.com/chemistry/journal/11814>.
