Abstract

In this article, a two-stage damage identification approach is employed to detect the site and extent of multiple damage cases in a 2D frame structure. In the first stage, Damage locating vector (DLV) method based on a new indicator called EDS (Exponential decreased stress) is applied to localize the damaged elements. Next, the damage extents of suspected elements are quantified using two metaheuristic algorithms, Water evaporation optimization (WEO) and accelerated WEO. Numerical example consists of a 2D frame structure with two types of meshing elements, 35 and 105 frame elements. For every state, two multiple damage cases are tested in noisy condition. To compare performance of the two-stage method with one-stage optimization method, the studied cases are also run using these two meta heuristic algorithms. The results indicate that the two-stage approach is more effective than one-stage because the number of intact ele ment detected as damaged one and computational errors for actual damaged elements in one-stage method are more while the two-stage approach spends a much shorter time.

1. Introduction

Many terrible accidents caused by unexpected damages in structures. SHM (Structural health monitoring) is extensively utilized to identify damage of structures and protect they better [1]. Many different methods of damage identification have been reviewed by researchers [2, 3].

Some typical methods work based on flexibility change [4, 5]. The Damage locating vector (DLV) is a kind of flexibility change method that firstly proposed by Bernal [6]. Many researchers developed the DLV method [7-9]. Quek et al. [8] proposed a new indicator called normalized cumulative en ergy (nce) and extended the DLV method. Vo-Duy et al. [9] employed the DLV and nce index to localize multiple damage sites in laminated composite beams. Dinh-Cong et al. [10] proposed a two-stage assessment method using DLV and Differential evaluation (DE) algorithm for damage detection of cross-ply laminated composite beams. Nguyen-Thoi et al. [11] utilized a combination of DLV and DE algorithm for structural damage assessment. Also, many researchers have tested optimization method and other methods to identify damage in engineering structures [12-17].

The DLV method can be used to localize damage sites and if the method is combined with an optimization method, the

resulting method will be a two-stage damage identification approach and can be utilized to localize and quantify damages. Some researchers utilized this type and other two-stage methods [18-22]. According to mentioned references, one-stage detecting damage methods have been commonly used among different methods in which researchers have allocated a long time for solving inverse optimization problem to assess dam age of damaged elements along with disruptive healthy elements. It decreases the accuracy of identifying damage extent while two-stage approaches have converted the process to two separate stages, locating damage elements and quantifying damage extent, by discriminating between damaged and healthy element and eliminating healthy elements.

In the current study, the application of DLV approach and two optimization algorithms, Water evaporation optimization (WEO) and accelerated WEO, to identify damages of a 2D frame structures has been studied. In the first stage, damaged elements of the structure are localized by employing DLV and using a new index called Exponential decreased stress (EDS). The EDS index is formulated based on axial stress of frame elements. This index increases the stress of intact elements and decreases the stress of damaged elements through exponent of the stresses. In the second stage, a metaheuristic algorithm quantifies damage extent of elements introduced as suspected in the first stage. To show robustness and reliability of this approach and proposed EDS, a 2D-frame with two type of meshing elements has been examined with noise; also the

considered scenarios have been run using nce index and the results have been shown. Then damage extent of suspected elements is quantified by WEO and accelerated WEO algorithms.

The sections of this study are as follows: In Sec. 2, theoretical description is presented. The Water evaporation optimization and accelerated WEO algorithms are presented in Sec. 3. Numerical examples are studied in Sec. 4. Finally, the conclu sion is given in Sec. 5.

2. Theoretical description

As before mentioned, this approach has two main stages: localizing damaged elements using DLV method and quantifying damage extent of suspected elements by an optimization algorithm.

It should be noted that the damage is identified using reduction in elasticity modulus of frame elements in this study.

2.1 Damage locating vector method and EDS index

Bernal (2002) proposed DLV (Damage locating vector) in which load vectors are obtained through created changes of where flexibility matrix and loading up the vectors into freedom degrees leads zero stress over damaged elements. Changes of flexibility matrix in the pre and post damaged states are utilized to design static force vectors. Structural flexibility matrix, F, using dynamic parameters of structure can be written: 2) proposed DLV (Damage locating vector)

$$
\widetilde{\mathbf{F}} \approx \sum_{i=1}^{nm} \frac{1}{\omega_i^2} \mathbf{\varphi}_i \mathbf{\varphi}_i^{\mathrm{T}}
$$
 (2)

For obtaining DLV vector, consider a number of load distribution whose application to freedom degrees of the healthy and damaged structures causes identical deformation. If we define the loads within an L matrix, we have:

$$
(\widetilde{\mathbf{F}}_h - \widetilde{\mathbf{F}}_d) \times \mathbf{L} = 0 \text{ or } \Delta \widetilde{\mathbf{F}} \times \mathbf{L} = 0 \tag{3}
$$

in which, *h* and *d* refer to intact and damaged states, respectively. There are two condition for above equation: First con dition $\Delta \tilde{F} = 0$, in this case, there is no damage in structure so $\Delta \tilde{F} \neq 0$, second $\Delta \tilde{F}$ is not full rank and L includes a number of vectors that makes the null space. To determine the vectors corresponding to null space of $\Delta \tilde{F}$, Singular value decomposition (SVD) is used as follows (Bernal 2002):

$$
\Delta \widetilde{\mathbf{F}} = \mathbf{U} \Sigma \mathbf{V}^{\mathrm{T}} = [\mathbf{U}] \begin{bmatrix} \mathbf{S}_{r_1} & \mathbf{0} \\ \mathbf{0} & \mathbf{S}_{r_n} \approx \mathbf{0} \end{bmatrix} \begin{bmatrix} \widetilde{\mathbf{V}}^T \\ \mathbf{L}^T \end{bmatrix}

According to the equation, L is the right null space of $\Delta \tilde{F}^n$ and DLVs. Loading every column of them onto freedom degrees makes zero stress in damaged elements. But many excessive intact elements are probably localized due to use DLV. To solve this problem, some researchers have used nce (Normalized cumulative en ergy) and ncs (Normalized cumulative stress) indices. $\Delta \vec{F} \stackrel{\text{SDD}}{=} U \Sigma V^{\dagger} = [U] \begin{bmatrix} S_{\uparrow} & 0 \\ 0 & S_{\uparrow_{\alpha}} \approx 0 \end{bmatrix} \begin{bmatrix} \nabla^{\dagger} \\ U^{\dagger} \end{bmatrix}$ (4)
 erec it is clear that $S_{\uparrow_{\alpha}} > S_{\uparrow_{\beta}} > ... > S_{\uparrow_{\alpha}}$. According to the

suation, L is the right null space of where it is clear that $S_n > S_n > ... > S_n$. According to the
equation, L is the right null space of $\Delta \vec{F}$ and DLVs. Loading
every column of them onto freedom degrees makes zero stress
in damaged elements. But many excessive iere it is clear that $S_n > S_n > ... > S_n$. According to the
attion, L is the right null space of $\Delta \mathbf{F}$ and DLVs. Loading
expression of them onto freedom degrees makes zero stress
damaged elements. But many excessive intact

Axial stresses of healthy and damaged frame elements usu ally are more and less than 1, respectively. The EDS index uses the point and increases the stress of healthy elements and decreases the stress of damaged ones through exponent of stresses. Thus, those elements which have least EDS are reported as suspected damaged elements. If *i*th column of L is applied to the structure, stress of elements is given by: resses of healthy and damaged frame elements usu-
ore and less than 1, respectively. The EDS index
oint and increases the stress of healthy elements and
the stress of damaged ones through exponent of

to uselgy satic bives vectors. So solutional incolumn gradient, *E* as the function of succession of structure can be written:
 F = $\frac{8\pi}{L}$ **φ**, **φ**, **F** is the mumber of structure can be written:
 F = $\frac{8\pi}{L$ It should be noted that the mode shapes of all Degrees of freedom (DOFs) are required to be measured. While measuring the full set of mode shapes is not needed. It is better to measure the mode shapes of the damaged structure in partial DOFs firstly. Then the incomplete mode shapes are expanded with all DOFs of the structure by some methods proposed in Refs. [24-26].

2.2 Optimization method

To estimate damage extent of suspected damaged elements, an inverse optimization problem should be solved. It should be noted that any metaheuristic algorithm such as Grey wolf optimizer algorithm [27], Teaching–learning-based optimization algorithm [28] and Flower pollination algorithm [29] etc.

can be used and it is possible that the results of these algorithms be better than results of WEO and accelerated WEO. But these two algorithms have been chosen because they have been introduced newly and not used in damage detection literature yet.

An objective function based on changes of structural modal flexibility is defined. Structural flexibility is more sensitive to damage than modal data including natural frequencies and mode shapes. According to these point, Perera et al. [30] proposed following objective function: S. *R. Hoseini Vaez and N. Fallah / Journal of Mechanical Science and Technology* 32 (3) (2018) 1125-1133

\nFor the droplet evaporation phase $(t > t_{max}/2)$, the objective function value of molecules (Fit'_i) is scaled to the range
\n50°, -20°] by using contact angle vector $(\theta(i)^t)$:
\n
$$
\theta(i)' = \frac{(\theta_{max} - \theta_{min}) \times (Fit'_i - Min(Fit))}{(Max(Fit) - Min(Fit))} + \theta_{min}.
$$
\n(14)
\nThen *DEP* is constructed as follows:
\n
$$
DEP_{ij}^t = \begin{cases} 1 & \text{if } rand_{ij} < J(\theta_i^{(t)}) \\ 0 & \text{if } rand_{ij} \ge J(\theta_i^{(t)}) \end{cases}
$$

where E_{min} and E_{max} equal -3.5 and -0.5 , respectively; *Min* and *Max* are minimum and maximum functions, respectively. Then *MEP* is constructed as follows:

$$
MEP_{ij}^{\prime} = \begin{cases} 1 & \text{if } rand_{ij} < \exp(E_{sub}(i)^{\prime}) \\ 0 & \text{if } rand_{ij} \ge \exp(E_{sub}(i)^{\prime}) \end{cases}
$$
(13)

where MEP_i^i is the updating probability for *j*th variable of *i*th water molecule in the *t*th iteration.

tive function value of molecules (Fit_i^t) is scaled to the range $[-50^\circ, -20^\circ]$ by using contact angle vector $(\theta(i)^t)$:

$$
\theta(i)' = \frac{(\theta_{\text{max}} - \theta_{\text{min}}) \times (Fit_{i}' - Min(Fit))}{(Max(Fit) - Min(Fit))} + \theta_{\text{min}}.
$$
 (14)

here
$$
E_{min}
$$
 and E_{max} equal -3.5 and -0.5, respectively; *Min*
d *Max* are minimum and maximum functions, respectively.
\nthen *MEP* is constructed as follows:
\n
$$
MEP_{ij} =\begin{cases}\n1 & \text{if } rand_{ij} < \exp(E_{sub}(i)^i) \\
0 & \text{if } rand_{ij} \ge \exp(E_{sub}(i)^i)\n\end{cases}
$$
\n(13)
\nhere MEP_{ij}^i is the updating probability for *j*th variable of
\nwater molecule in the *t*th iteration.
\nFor the droplet evaporation phase ($t > t_{max}/2$), the objective function value of molecules (Fit_i^i) is scaled to the range
\n50°, -20°] by using contact angle vector ($\theta(i)^i$):
\n
$$
\theta(i)^i = \frac{(\theta_{max} - \theta_{min}) \times (Fit_i^i - Min(Fit))}{(Max(Fit) - Min(Fit))} + \theta_{min}.
$$
\n(14)
\nThen *DEF* is constructed as follows:
\n
$$
DEP_{ij}^i =\begin{cases}\n1 & \text{if } rand_{ij} < J(\theta_i^{(i)}) \\
0 & \text{if } rand_{ij} \ge J(\theta_i^{(i)})\n\end{cases}
$$
\n
$$
J(\theta) = J_0 P_0 (\frac{2}{3} + \frac{\cos^3 \theta}{3} - \cos \theta)^{-2/3} (1 - \cos \theta)
$$
\n(15)
\n
$$
J_0 P_0 = \frac{1}{24}
$$
\nhere *MEP_{ij}^i* is the updating probability for *j*th variable of
\nwater molecule in the *t*th iteration; J_0 and P_0 are constant
\nlues; *J* is evaporation flux where maximum and minimum
\nline of it are 1 and 0.6, respectively.

where MEP_i^i is the updating probability for *j*th variable of *i*th water molecule in the *t*th iteration; J_0 and P_0 are constant values; *J* is evaporation flux where maximum and minimum value of it are 1 and 0.6, respectively.

(11) *3.1.3 Generating random permutation based step size matrix* A random permutation based step size matrix is defined as

follows:

$$
S = rand. (WM^{(i)}[p1(i)(j)] - WM^{(i)}[p2(i)(j)])
$$
 (16) end
_{[a,b]=sort(**dist**);}

S. R. Hoseini Vaez and N. Fallah / Journal of Mechanical Science and Technology 32 (3) (2018) 1125-1133

lows:
 $S = rand. (WM^{\omega} [p1(i)(j)] - WM^{\omega} [p2(i)(j)])$ (16) $\frac{ad}{[a,b]=sort(dist)}$

ere p1 and p2 are different rows permutation functions where *p*1 and *p*2 are different rows permutation functions; *i* and *j* are the number of water molecules and design variables of the problem, respectively; *WM* is the evaporated set of water molecules.

3.1.4 Generating evaporated water molecules and updating the matrix of them

The evaporated set of water molecules $(WM^(t+1))$ is generated according to the product of step size matrix and evapora-

tion probability matrix: (1) () () max () max *t t t ^t WM Round WM S* £ > (17)

The rounding function rounds the design variables' values to the nearest discrete available value. The best individual is returned after evaluating the molecules based on the objective function.

3.1.5 Terminating condition check

Steps 2 to 4 are continued to repeat until termination condition, number of iterations (*t*), is met.

3.2 Accelerated WEO

In accelerated WEO, updating molecules is worked by using monolayer and droplet evaporation phases simultaneously. Steps of the accelerated WEO implementation are as follows:

3.2.1 Initializing algorithm parameters

In this step, the worst water molecule (Worst-WM) in objective function value terms is monitored in addition to detail of the one described in the WEO.

3.2.2 Generating water evaporation matrix

Firstly, the distance vector between all individuals and the worst current one (*dist*) is calculated:

$$
dist_i = |worstWM - WM_i|, i = 1, 2, ..., nWM.
$$
 (18)

The individuals are sorted based on their distance values in ascending order. Then the DEP and MEP matrices are calculated for updating the first and second half of the molecules, respectively, by using Eqs. (13) and (15). It should be noted that the evaporation and droplet probability matrices and their corresponding details, contact angle vectors and substrate energy include *nWM*/2 rows. Then mixed evaporation matrix (MDEP) is assembled using the pseudo code shown in Fig. 1.

for $i=1:nWM$

end

 dist(*i*)=norm(*WM*(*i*,:)-*worst-WM*); end

for *i*=1:*nWM*/2

$$
droplet-WM(i,:)=WM(b(i),:);
$$

Generate the corresponding *θ* vector and *DEP* matrix using Eqs. (14) and (15), respectively.

for $i=1$ *:* n *WM*/2.

 $\mathbf{monolayer-WM}(i,:) = \mathbf{WM}(b(\text{size}(nW\text{M}/2+i))$; end

Generate the corresponding E_{sub} vector and **MEP** matrix using Eqs. (12) and (13), respectively.

                                                                                                                                                                              MDEP (b(i),:) = <i>MEP</i>(i - size(<i>WM</i>,1)/2, :); end
                                                                                                                                                  end
```
Fig. 1. Pseudo code for constructing the MDEP matrix.

3.2.3 Generating random permutation based step size matrix

In this step, a random permutation based step size matrix is calculated same as the one described in the WEO.

3.2.4 Generating evaporated water molecules and updating the matrix of them

The evaporated set of individuals $(WM^{(t+1)})$ is generated ac-

$$
WM^{(t+1)} = Round(WM^{(t)} + S \times MDEP^{(t)})
$$
 (19)

Then the best molecule is returned after evaluating the molecules corresponding to their objective function values.

3.2.5 Terminating condition check

Steps 2 to 4 are continued to repeat until termination condition, number of iteration of the algorithm (*t*), is met.

4. Numerical example

.5. Terminating condition check

Steps 2 to 4 are continued to repeat until termination condi-
 interactive of the matrix of the matri In this section, to demonstrate the ability of EDS and the algorithm, a 2D frame structure with two different meshing using some multiple cases are studied. For each state, two multiple cases with two and four damaged elements are con sidered. For each case, the EDS of all elements with various numbers of modes (6, 8 and 10 first modes) are shown in noisy condition. To precisely localize damaged elements, the DLV and the algorithms have been run 30 times for every case. Then mean EDS values of elements are shown. Also the mean and the best (with least value of objective function) solutions of the algorithms, damage severity of suspected elements, have been reported. To compare of the two-stage method with optimization method, the studied cases are also run using optimization method (within one step and solving an

inverse optimization problem) in noisy condition and the results are reported. Although existence of many number of modes helps the algorithms easily converge the right state of damage in the second stage, it increases the rate of program running and results in more time to the algorithms. Therefore, the number of considered modes in the objective function should be selected in a way that induces appropriate balance for the algorithms. For running algorithms in this approach, the six first modes have been utilized for all cases which is equal to lowest number of considered modes for the first stage. The number of iterations and population sizes are considered as 100 and 50, respectively. The physical properties of the frame's elements are given in Table 1. Also the length of every element in the first and second meshing states is 1 and 1/3 m, respectively. Error values considered to generate noisy data of natural frequencies and mode shapes are 1 % and 3 %, respectively, as follows [13]: ts are reported. Although existence of many number of

dods helps the algorithms casily converge the right state of

mage in the second stage, it increases the rate of program

in which *noisy* implies a noisy value; α is a uniformly distributed randomly number between -1 and +1.

4.1 Frame with 35 elements

This structure was investigated in the field of damage detection by Mousavi and Gandomi [26]. The frame includes 35 elements and 24 joints as shown in Fig. 2. In the figure, the damaged elements of cases are bolded. The details of two damage cases with multiple damage extent is given in Table 2.

For the two cases, EDS of all elements in noisy condition have been shown in the Figs. 3 and 4. Also, the NCE values of all elements in noisy condition have been shown in the Figs. 5 and 6.

The Figs. 3 and 4 show that the EDS of damaged elements is less than others and they are identified as suspected dam aged elements. Also, the figures show that the more number of modes is used, the higher precision in measurement of EDS becomes obtained and damaged elements are identified better. According to the Figs. 5 and 6, the NCE index has not been able to detect all of the damaged elements in second scenario.

Tables 3 and 4 show damage extents of suspected damaged elements estimated by WEO and accelerated WEO algorithms within 30 runs.

Fig. 7. Frame with 105 elements.

Fig. 8. The EDS values of the frame with 105 elements for first case in noisy condition.

4.2 Frame with 105 elements

The frame includes 105 elements and 94 joints as shown in Fig. 7. In the figure, the damaged elements of cases are bolded. The details of two damage cases with multiple damage extent is given in Table 5.

For the two cases, EDS of all elements in noisy condition have been shown in the Figs. 8 and 9. Also, the NCE values of all elements in noisy condition have been shown in the Figs. 10 and 11.

According to the Figs. 10 and 11, the NCE index has not been able to detect all of the damaged elements in second scenario. So efficiency of the NCE index is low in finding the damaged elements corresponding to scenario with more dam aged elements.

According to the results, the EDS values of damaged elements in all scenarios for eight first modes are low enough to identify them. So the efficient number of modes required to

Accelerated	Best	0.25	0.19
WEO	Mean	0.25	0 19

Table 7. Damage extents of suspected damaged elements for second scenario of frame with 105 elements.

4.3 Comparing the approaches' performance

To show ability of the two-step and optimization approaches to find damage site and quality damage extent, the all of the cases are also run using the algorithms within one step. For running algorithms in this approach, the six first modes have been utilized for all cases; the number of iterations and population sizes are considered as 1000 and 500, respectively. The best results (with least value of objective function) are shown in Tables 8 and 9 for the frame with 35 and 105 elements, respectively. The misidentified elements found by the algorithms are underlined for a better under standing of the results in the Tables 8 and 9.

For the frame with 35 elements, the values less than 0.01 have been considered equal to zero. About the frame with 105 elements, the values less than 0.03 and 0.05 have not been reported for WEO and accelerated WEO algorithms, respectively, because they were many. According to Tables 8 and 9, most of the misidentified values relates to element 62 (0.18) corresponding to Case 2 and accelerated WEO algorithm. As it is clear, the number of misidentified elements is high especially in cases with four actual damaged elements. These values demonstrate that the optimization method is not efficient when the elements of structure or damaged elements are more while spends too time for solving inverse optimization problem. Also, it is concluded that because of less number of algorithm's variables in two-stage approach, type and efficiency of an algorithm is less important than in one-stage optimization method.

On comparing the performance of these two algorithms in one-step method, the sum errors of misidentified elements obtained from accelerated WEO is more than WEO. Also, computational errors for actual damaged elements corresponding to WEO is less than accelerated WEO. Thus the perform ance of WEO is better than accelerated WEO in running one-

step method.

5. Conclusions

In this paper, a two-stage approach based on DLV (Damage locating vector) and two metaheuristic algorithms, Water evaporation optimization (WEO) and accelerated WEO, is employed to identify damage of a 2D frame structure. In the DLV method, suspected damaged elements are found by a new proposed index called EDS (Exponential decreased stress) according to axial stress of elements. Numerical exam ple including two types of meshing elements is examined by different multiple cases. Also the cases are tested by one-stage [8] S. Quek, V. Tran, X. Hou and W. Duan, Structural damage optimization method and using these two algorithms. Results conclude that the two-stage method are efficient especially in the frame with more elements and damaged elements. The error in computation of damage extent for suspected damaged elements and misidentified elements corresponding to one and two-stage approach are 0.180 and 0.002, respectively.

Seyed Rohollah Hoseini Vaez is currently an Assistant Professor at the University of Qom. He teaches courses on the finite element methods, structural optimization, advanced reinforced con crete structures and earthquake engineering. Dr. Hoseini Vaez's research interests include damage detection,

finite element method, optimization algorithms and soft com puting.

Narges Fallah received B.Sc. degree in civil engineering from Qom University, Iran, in 2014 and a M.Sc. in 2016 in structural engineering. She is currently a Ph.D. student in Structural Engineering at the University of Qom. Fallah's research interests include SHM and metaheuristic algorithms.
