ABSTRACT

A highly porous and crystalline metal–organic framework (MOF) ZIF-8 has been synthesized and used for the preparation of a supported rhodium nanoparticle catalyst (Rh@ZIF-8). The material has been characterized by PXRD, TEM, EDX, ICP–AES and nitrogen adsorption. The catalytic properties of Rh@ZIF-8 have been investigated in the hydroformylation of alkenes, with different chain length and structure, to give the corresponding aldehydes, and showed high activity. Furthermore, after the reaction was complete, the catalyst could be easily separated from the products by simple decantation and reused five times without a significant decrease in the activity under the investigated conditions.

The hydroformylation or oxo reaction employed for the synthesis of aldehydes and alcohols starting from alkenes is an important reaction from both industrial and academic perspectives [1–5]. All current commercial hydroformylation processes are based on homogeneous catalysts, mostly using rhodium complexes, which have supplanted cobalt derivatives due to their higher activity [3–5]. These processes also use phosphine or phosphite ligands to increase the regioselectivity towards the desired linear or branched aldehyde [6–14]. Although homogeneous catalysts give high conversion and selectivity for desired product in

short reaction times, they suffer from the problems of separating the catalyst from the reaction mixture and catalyst recycling. Thus, the development of a successful heterogeneous catalyst would allow a much simpler industrial production process to be implemented. Research efforts are directed towards the heterogenization of rhodium/cobalt complexes for hydroformylation of alkenes. The attachment of homogeneous catalysts to polymeric organic, inorganic or hybrid supports are such examples [15–20]. Although such catalysts can be recycled and easily separated from the reaction mixtures, they are usually

Address correspondence to ydli@mail.tsinghua.edu.cn

significantly less catalytically active and less thermally stable than their homogeneous analogues and also require complicated synthesis procedures [21]. Thus the development of a practical heterogeneous catalyst, such as supported rhodium nanoparticle catalysts, is highly desirable.

Metal–organic frameworks (MOFs) are a new class of hybrid porous materials assembled with metal cations and organic ligands. By controlling the size and functionalization of the organic linkers, well-defined MOF structures with high surface areas and tunable pore sizes can be achieved, thus offering advantages over traditional microporous and mesoporous inorganic materials [22–26]. Owing to their high surface area and porosity, the uses of MOFs as supports for metal (e.g., Pd, Au, Ru, and Pt) nanoparticles (NPs) have recently received tremendous attention [27–32]. Furthermore, some NPs@MOFs have exhibited excellent catalytic activities in organic reactions due to the confinement effect of the substrate in a MOF which means the particles remain constrained and do not grow further after catalytic reactions [31–34]. By virtue of its high chemical and thermal stability (550 °C in N₂) and large surface area (ranging from 1,100 to 1,810 m²·g⁻¹), ZIF-8 (Zn(mim)₂, mim = 2-methylimidazolate), a zeolite-type MOF, has become the most promising candidate as an effective matrix to control the particle size of NPs and improve their catalytic surface area for heterogeneous catalysis [35–39]. Herein, a highly porous and crystalline MOF ZIF-8 has been synthesized and used for the preparation of a supported rhodium nanoparticle catalyst. The material has been characterized by XRD, TEM, EDX, ICP–AES and nitrogen adsorption. The catalytic properties of Rh@ZIF-8 have been investigated in the hydroformylation of alkenes with different chain length and structure to the corresponding aldehydes, and showed high activity. It is worth noting that the Rh@ZIF-8 catalyst can be separated easily by filtration after reaction and be reused several times without significant loss in activity.

ZIF-8 was synthesized according to the reported method [35]. The synthesized ZIF-8 was activated and then added to a solution of RhCl₃ under vigorous agitation. The mixture was then reduced with freshly prepared aqueous NaBH₄ solution at 273 K. The solid

was centrifuged and washed with three times with EtOH, and the resulting Rh@ZIF-8 was dried under vacuum (more details are given in the Electronic Supplementary Material (ESM)). The PXRD patterns of the synthesized ZIF-8 and Rh@ZIF-8 are similar to the simulated pattern of ZIF-8 (Fig. 1) reported by Yaghi et al. [36]. Both materials have high crystallinity and the sharp and strong peaks at 5–10° reveal the presence of micropores. The XRD pattern of Rh@ZIF-8 (Fig. 1(c)) did not show the characteristic diffraction peaks of rhodium metal, suggesting that the rhodium nanoparticles are finely dispersed. An alternative explanation is that the signal is below the detection limit because of the relatively low Rh loading [40]. In addition, the XRD pattern of Rh@ZIF-8 after reaction showed that the main diffraction peaks were consistent with those of pristine ZIF-8, indicating that the framework of ZIF-8 was maintained during the process of catalytic hydroformylation (Fig. 1(d)).

N₂ sorption isotherms of both samples are of type I (Fig. 2). The pore volumes of ZIF-8 and Rh@ZIF-8 calculated from their adsorption isotherms are 0.592 and 0.506 cm³·g⁻¹, respectively. The decrease in pore volume (about 0.086 cm³·g⁻¹) suggests that Rh enter through the pore windows and partially occupy the pores. The calculated BET surface areas of ZIF-8 and Rh@ZIF-8 are 1,366 and 1,178 m²·g⁻¹, respectively. The reduction in surface area is also attributed to the incorporation of Rh in the pores of ZIF-8 [31, 32].

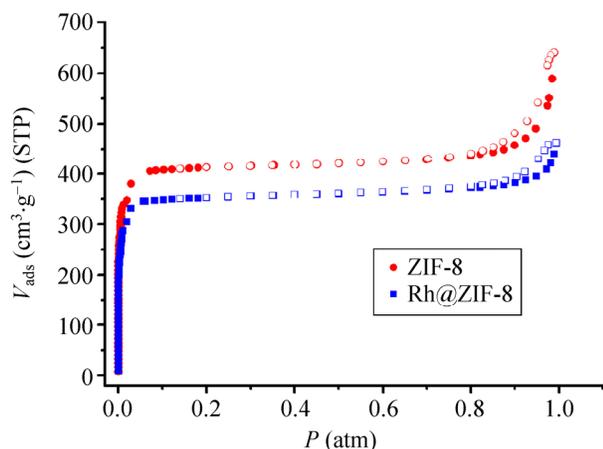

Figure 2 N_2 sorption isotherms of as-synthesized ZIF-8 and Rh@ZIF-8. Filled and open symbols represent adsorption and desorption branches, respectively.

To determine the particle size distribution, we conducted TEM analysis on Rh@ZIF-8. Figure 3 shows typical TEM images of Rh@ZIF-8. The low magnification image (Fig. 3(a)) shows the morphology of ZIF-8, but could not clearly show the Rh NPs, which indicate that the ZIF-8 immobilized Rh NPs were highly dispersed and have small sizes. The EDS of the sample shows the presence of Rh (Fig. S1 in the ESM). High-annular dark-field scanning TEM (HAADF-STEM) (Fig. 3(b)) provides direct evidence that the highly dispersed Rh NPs have been effectively immobilized by ZIF-8 and constrained to have small sizes. Clearly, the microporous structure of ZIF-8 favors the formation of small rhodium nanoparticles, probably due to a high dispersion of the precursor Rh^{3+} ions through weak π -interaction with the 2-methylimidazole linkers [31].

Catalytic activity of the Rh@ZIF-8 catalyst was evaluated in the hydroformylation of linear alkenes

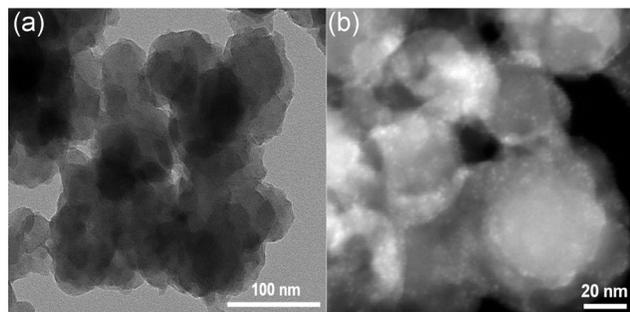

Figure 3 (a) TEM image and (b) HAADF-STEM image of Rh@ZIF-8.

with different chain lengths and structure, and the results are listed in Table 1. It should be noted that the analysis of the reaction products shows that beside *n*- and iso-aldehydes as the desired reaction products, double bond shifted internal alkenes are also formed as side products by isomerization. No significant hydrogenation of alkenes to saturated alkanes was observed. The blank experiments with *n*-hexene and *n*-octene show that the parent ZIF-8 (without rhodium) does not catalyze the double bond isomerization of *n*-alkenes to internal alkenes or the hydroformylation of alkenes to aldehydes even after reaction for 24 h of entry 3. The *n*/*iso* ratio of aldehydes was observed in the range of 0.4–0.9. Both the yield of aldehydes and the *n*/*iso* ratio are independent of carbon chain length of alkenes under our reaction conditions.

The effect of syngas pressure on the reaction was studied (Table 2). In the range from 1.0 to 5.0 MPa, as shown in Table 2 (entry 1 to entry 5), the aldehyde yield increased with increasing pressure and 81% aldehyde yield was achieved at 5.0 MPa. The *n*/*iso* ratio (0.6–3.0) obtained with the Rh@ZIF-8 catalyst was in agreement with the results reported by Dupont and co-workers using Rh nanoparticles [41].

It was also clear from the data in Table 2 that prolonged reaction time led to an increase in aldehyde yield (entry 5 to entry 9). It is worth noting that the yield of aldehydes increased sharply but the *n*/*iso*-ratio decreased when the reaction time was prolonged from 1 to 5 h (entry 5 to entry 9), which is in agreement with the results reported by Vu and co-workers [42, 43].

Table 1 Hydroformylation of different alkenes catalyzed by Rh@ZIF-8

Entry	Alkene	Yield of aldehydes (%)	Yield of iso ^a (%)	Yield of n ^b (%)	<i>n</i> / <i>iso</i>
1	1-Hexene	92	48	44	0.9

The lifetime is an important aspect concerning the use of catalysts, and therefore the reusability of the Rh@ZIF-8 was examined (Fig. 4). After reaction, the catalyst was separated from the reaction solution by simple filtration in air after the reaction. The separated catalysts were all washed by isopropanol under ultrasonic washing and used in the next reaction run. The recovered Rh@ZIF-8 exhibited high catalytic efficiency without evident loss of activity after the catalyst was reused five times (Fig. 4). The stability of Rh@ZIF-8 may be due to the good dispersion of the Rh nanoparticles [44, 45].

In summary, highly dispersed Rh NPs with small particle sizes have been successfully immobilized in the frameworks of ZIF-8, and exhibit high catalytic activity for the hydroformylation of n-alkenes. Furthermore, after the reaction was completed, the catalyst

**Figure 4** Reusability of Rh@ZIF-8 catalyst for hydroformylation of 1-heptene.

could be easily separated from the products by simple decantation and reused five times without a significant decrease in activity under the investigated conditions. These highly efficient catalysts, which can be separated easily after reaction, represent a promising step toward the practical applications of MOFs as effective matrices to immobilize Rh NPs in the catalytic hydroformylation reaction system.
