

Dynamic Stability Enhancement Using Fuzzy PID Control Technology for Power System

Khaled Eltag, Muhammad Shamrooz Aslam*, and Rizwan Ullah

Abstract: This article presents Fuzzy Particle Swarm Optimization of PID controller PSO-FPIDC used as a Conventional Power System Stabilizer CPSS to improve the dynamic stability performance of generating unit during low frequency oscillations. Speed deviation $\Delta\omega$ and acceleration $\Delta\dot{\omega}$ of synchronous generator are taken as input to the PSO-FPIDC controller connected to Single Machine Infinite Busbar SMIB system. This controller examined under different perturbation scenarios. The dynamic performance of the PSO-FPIDC is compared with the Fuzzy Teacher Learner Based Optimization PID TLBO-FPIDC, PSO-PID, TLBO-PID and optimal parameters of conventional Power System Stabilizer CPSS. The results show that the performance of PSO-FPIDC has small overshoot/undershoot and damp out lower frequency oscillations very quickly as compared to other controllers.

Keywords: Dynamic stability, fuzzy PID control, power system stabilizer, PSO, single machine infinite bus, TLBO.

1. INTRODUCTION

Stability of the synchronous generator in electrical power system will be lost by an aperiodic deviation of rotor angle, or due to speed deviation oscillatory. These oscillations may sustain and grow due to insufficiency of damping torque. Power System Stabilizers PSS are present a damping torque for the purpose of reducing these oscillations caused by external perturbations by supply signal to excitation system and/or the speed governor system of the generating unit. The optimization techniques for tuning parameters of these devices in [1–4]. Most types of PSS utilize the classical linear control theory based on a linear model which has constant-parameters. Low-frequency oscillations are a wide spread problem in power systems at the same time power system are nonlinear and its parameters change with time [5–7]. Because PSS introduce complexity by introducing new states to the system. Therefore we use Proportional Integral Derivative PID controller optimized by intelligent techniques such as TLBO and PSO. For real time fast response fuzzy logic technique is applied in this work PSO-FPIDC.

Proportional integral derivative PID controllers are being popularly used by the industries for their simplicity and robustness. Through the growth of control theorems and technologies, today's conventional PID control technology has been perfectly overripe, it has unpretentious algorithm, obvious installation, comfortable setting, affluent expertise in application and other features [8, 9]. The

parameters of this controller are fixed, can not be real-time compromised. Due to this various evolutionary and swarm intelligence based tuning methods have been proposed in literature [10–12]. The TLBO is applied for optimizing various engineering problems [13–15].

Fuzzy Logic Control FLC has arisen as a powerful tool and it starts to be implemented in various power system applications. The application of fuzzy logic control technique becomes clear to be most suitable one whenever a well-defined control objective cannot be identified clearly, the system to be controlled is a complex, or its exact mathematical model is not obtained [16, 17]. FLC has a fixed set of control rules, usually derived from experts knowledge. The Membership Functions MFs of the associated input and output linguistic variables are generally predefined on a common universe of discourse. The investigation of adaptive fuzzy optimal control/filtering problems introduced in [18–26].

In this paper presents Particle Swarm Optimization Fuzzy PID controller PSO-FPIDC instead of Conventional Power System Stabilizer CPSS in Single Machine Infinite Busbar System SMIB, where the parameter of PID controller optimized by particle swarm optimization and Fuzzy logic Controller. Speed change $\Delta\omega$ and acceleration $\Delta\dot{\omega}$ of the rotor were taken as input to PSO-FPIDC controller to improve the dynamic stability performance of SMIB system, the system examined under different perturbations. The performance of the PSO-FPIDC is compared with the Fuzzy Teacher Learner Based Optimization

TLBO-FPIDC, PSO-PID, TLBO-PID and optimal parameters of convectional Power System Stabilizer CPSS. The result shows that the performance of PSO-FPIDC has small overshoot/undershoot and damp out oscillations quickly as compared to other controllers.

2. PROBLEM PRESENTATION

Electric power systems configurations are quite nonlinear and over sensitive to be coming unstable if any sudden change occurred in the system operation. Power systems parameters are change with time. However the parameters of PSS will not change in real time. Accordingly PSO-FPIDC as power system stabilizer is used in this work. The Single Machine Infinite Busar SMIB with transmission-circuit reactance Fig. 1. In order to achieve the stability enhancement, speed change $\Delta\omega$ and acceleration $\Delta\dot{\omega}$ of SMIB is considered as input to PSO-FPIDC controller as presented in Fig. 2. The linear model of SMIB mostly used to study the performance of dynamic stability of electrical power system which contains the relationship of electromechanical torque between angle and speed changes of generating unit [27], Automatic Voltage Regulator AVR [6], high gain IEEE type ST1A model of the static excitation system is considered and transmission-circuit reactance is presented by a two axis, fourth order model is shown in Fig. 2 [6]. The PSO-FPIDC structure connected with rotor speed change as input has made a very nice contribution to improve system dynamic stability. where $\Delta\omega_r$, $\Delta\delta$ and $\Delta\psi_{fd}$ are speed change, rotor angle change and field flux change respec-

tively. ΔE_{fd} , ΔT_e and ΔT_m represent field voltage change, electrical torque change and mechanical torque change respectively. ΔV_s , ΔV_1 , V_{ref} and ΔE_t represent voltage transducer change, reference voltage change and terminal voltage change respectively. $G_{ex(s)} = K_A$, is the transfer function of exciter. Finally, K_A , K_1 , ..., K_6 , H , K_D , T_3 , and T_R are parameters of system [6], they are functions of active power P with the exception of H .

3. PSO OPERATION PRINCIPAL

Particle Swarm Optimization (PSO) algorithm is the optimization technique developed by Dr. Kennedy and Dr. Eberhart [28]. It is a multi-swarms search for best solution of object function and updating swarm values. In the Dimension-axis study of search area [29], the i^{th} swarms position represented by $X_i = (X_{i1}, \dots, X_{im})$. The i^{th} swarm velocity of Dimension vector represented by $V_i = (V_{i1}, \dots, V_{im})$. The best position given by the i^{th} particle is calculated as $P_i = (P_{i1}, \dots, P_{im})$ and P_g is position index of the particle found in the swarm previous position, then P_g become to be the global best position calculated, the particle velocity and new position will be calculated by using the following equations:

$$V_{im} = WV_{im} + C_1 r(P_{im} - X_{im}) + C_2 R(P_{gm} - X_{im}), \quad (1)$$

$$X_{im} = X_{im} + V_{im}, \quad (2)$$

where C_1 and C_2 are Personal and social Acceleration factors positive constants, and r is random values in interval $[0,1]$. The parameter W is the Inertia factor that increases the overall performance of PSO.

4. PID CONTROLLER TUNING USING (PSO)

The optimization problem is to optimize the PID controller and calculate the minimum value of object function. The object function would minimize steady state error E_{SS} , over-shoot M_p , rise-time t_r and settling-time t_s as presented in following (3) [30]:

$$F = (M_p + E_{SS})(1 - e^{-1.5}) + (t_s - t_r)e^{-1.5}. \quad (3)$$

Step 1: Define the parameters of PSO algorithms: number of iterations, swarm size, acceleration factors, inertia factor, the position matrix P_i and the velocity matrix V_i and constraints of K_P , K_I and K_D .

Step 2: Initialize value of each particle.

Step 3: Compare between new and old fitness particle's personal position, after that update the personal best position's which called P_{best} .

Step 4: Continue Search for best P_{best} through all particles. And denote the best position as G_{best} .

Step 5: Update the V_i in (1), and P_i in (2).

Step 6: Update PID controller parameters.

Step 7: If reach the maximum iterations, then stop. The latest G_{best} is the optimal PID controller parameter. Otherwise, go to Step 2.

5. TLBO OPERATION

The teacher learner based optimization TLBO is proposed by Rao [31]. It has two phases, first one is teacher phase where teacher tries to improve the learners to his level. the second one is learner phase where learners interacts to improve their performance.

5.1. Teaching phase

Consider $X_t^i (i = 1, 2, \dots, m)$ is the i^{th} learner in the population, X_t^{best} is the best learner in the current iteration L . The $Mean_{t,j}$ is the value of mean result of learners in a particular subject $j (j = 1, 2, \dots, n)$, T_F is the teaching factor and r_t is the random number which can be any value between 1 or 2. In a problem with n dimension, at any iteration t , we have the following notations as given in [32]:

Step 1: First compute the difference $D_{t,j}$ between the teacher (best learner) by taking random number r_t in the range $[0,1]$:

$$D_{t,j} = r_t(X_{t,j}^{best} - T_F Mean_{t,j}). \quad (4)$$

Step 2: Learner X_t^i update its state in subject j by combining the difference $D_{t,j}$ and its current state:

$$X_{t,j}' = X_{t,j}^i + D_{t,j}. \quad (5)$$

Step 3: If X_t^i , is better then replace the latter by the new value.

5.2. Learning phase

Step 1: For the learner X_t^i , randomly choose another learner X_t^k , if X_t^i is better than X_t^k , then:

$$X_t^i = X_t^i + r_i(X_t^i - X_t^k). \quad (6)$$

Step 2: If X_t^k is better than X_t^i , then let:

$$X_t^i = X_t^i + r_i(X_t^k - X_t^i). \quad (7)$$

Step 3: If X_t^i is better than X_t^i , then replace the better by the new value.

6. PID CONTROLLER TUNING USING TLBO

The steps of the proposed TLBO algorithm as follows:

Step 1: Define the lower and upper bounds of K_P , K_I and K_D , number of iteration, population size (learners).

Step 2: Choose the best learner X_t^{best} as a teacher.

Step 3: Evaluate the difference $D_{t,j}$ in (4).

Step 4: Update learners by teacher knowledge (5).

Step 5: Update learners by other learner knowledge (6)-(9).

Step 6: Stop if a stopping criteria is achieved, else go to Step 3.

Fig. 3. Fuzzy PID Control System Structure connected to SMIB.

7. ADAPTIVE FUZZY-PID CONTROLLER PRINCIPLE

The fuzzy PID controller optimized by intelligent techniques is robust way to obtain real time fast dynamic response when sudden operating condition change occurred in power system. The PSO-FPIDC/TLBO-FPIDC controller is shown in Fig. 3. fuzzy controller has two inputs speed change $\Delta\omega$ and acceleration $\Delta\dot{\omega}$ of SMIB, through fuzzification, fuzzy inference and deblurring the controller output is adapted. The parameters $G_{\Delta\omega}$ and $G_{\Delta\dot{\omega}}$ are scale value to drive $\Delta\omega$ and $\Delta\dot{\omega}$ into the fuzzy domain, where GK_P , GK_I , GK_D are the scale values calculated by fuzzy to drive control quantity into the domain of the control object as factors of K_u . The domain of $\Delta\omega$, are respectively $[-\Delta\omega_{max}, \Delta\omega_{max}]$ and $[-\Delta\dot{\omega}_{max}, \Delta\dot{\omega}_{max}]$, The domain of the output is $[-u_{max}, u_{max}]$. In (8) n and m are the maximum output values of fuzzy domain, l_1, l_2, l_3 is the large calculated fuzzy value for K_u .

$$G_{\Delta\omega} = \frac{n}{\Delta\omega_{max}}, \quad G_{\Delta\dot{\omega}} = \frac{m}{\Delta\dot{\omega}_{max}}, \quad GK_P = \frac{u_{max}}{l_1},$$

$$GK_I = \frac{u_{max}}{l_2}, \quad GK_D = \frac{u_{max}}{l_3}. \quad (8)$$

8. DETERMINE OF MEMBERSHIP DEGREE

In the conventional (PID) controller formula [33] is:

$$U(t) = K_P e(t) + K_I \int_0^t e(t) dt + K_D \frac{de(t)}{dt}. \quad (9)$$

After PSO-PID parameter optimized by fuzzy controller, the parameters into real time variable, so the control can be written as:

$$U(t) = (K_P + \Delta K_P) e(t) + (K_I + \Delta K_I) \int_0^t e(t) dt$$

$$+ (K_D + \Delta K_D) \frac{de(t)}{dt}. \quad (10)$$

In (9) and (10) $e(t) = \Delta\omega$, ΔK_P , ΔK_I , ΔK_D is ($K_u \times GK_u$) type the membership of each state determined, this ac-

Fig. 4. Membership functions of (a) $\Delta\omega$, $\Delta\dot{\omega}$. (b) Membership function of ΔK_p , ΔK_I , ΔK_D .

according to experiment personal experience. Here the domain $\Delta\omega$ and $\Delta\dot{\omega}$ is $[-6, -4, -2, 0, +2, +4, +6]$, the domain of output is $[-3, -2, -1, 0, +1, +2, +3]$, linguistic variables of the output are *NB* (negative big), *NM* (negative middle), *NS* (negative small), *Z* (zero), *PS* (positive small), *PM* (positive middle), *PB* (positive big). The membership functions are as shown in Fig. 4 [34].

9. THE FUZZY RULES DESIGN

Fuzzy rules are The core of a fuzzy controller, the object of this rules is to optimize real time parameters of PSO-FPIDC/TLBO-FPIDC controller, the fuzzy rule is depend on expert designers engineers. The convectional PID controller parameter related to characteristic curve, then PID parameter tuning rules set as follows [35]:

1) When the input of PID $\Delta\omega$ is big the speed deviation should be decreta controlled object is established, and the input large, should cancel to realize stability as quickly as possible to improve the dynamic response of system controlled, thus we have to select the big K_p , and we must be careful to avert big $\Delta\omega$ rate differential saturation, so take K_D smaller, this also important to avert big overshoot, so we should take $K_I = 0$.

2) In the medium change of the $\Delta\omega$ and $\Delta\dot{\omega}$ we must minimize the GK_p , GK_I and GK_D and use suitable values.

3) In the system is stable which means the $\Delta\omega$ and $\Delta\dot{\omega}$ is a little, so we must increase the GK_p and GK_I , to enhance the system dynamic, and we must be careful to avert the steady state error, so GK_D effect is very necessary, and generally $\Delta\dot{\omega}$ can take larger GK_D and the large $\Delta\omega$ can take smaller GK_p . Related to the pervious tuning steps, then the fuzzy rules shown in Table 1 to Table 3.

10. SIMULATION RESULTS

The proposed controller is applied to a Single Machine Infinite Busbar SMIB power system as shown in Fig. 2. To improve the dynamic stability performance of power system. Speed deviation $\Delta\omega$ and acceleration $\Delta\dot{\omega}$ of the rotor of synchronous generator were taken as input to Particleation Fuzzy PID controller PSO-FPIDC and other type of controllers in stead of conventional power system stabilizer CPSS. Each input has eight fuzzy logical sets [NB,

age V_{ref} or in mechanical torque T_m simultaneously. The simulation is implemented in MATLAB 17a software.

For the sake of comparison to show the potential merits between the proposed approach The PSO-FPIDC compared with PSO-PID, TLBO-FPIDC, (TLBO-PID) and optimal parameters were determined for CPSS K_s , T_1 and T_2 where these parameters presented in reference [36, 37]. The parameters of all controllers shown in Table 4. Simulation studies are carried out corresponding to an operating condition of $P = 0.5$, $Q = 0.2$, $X_e = 0.93$, $E_t = 1.0$ (all are in pu) for 1.0 pu under simultaneous change in ΔT_m and ΔV_{ref} . The dynamic responses shown in Figs. 11-16. The comparison between output controller response presented in Figs. 8-10. It is observed from these figures that the proposed controller guarantee stable. Therefore, the PSO-FPIDC controller has the capability to achieve the most

Fig. 7. Convergence of $PSO/TLBO$ under 500 iterations.

(minimum speed oscillations), most stable accurate (minimum O_{sh}/U_{sh}) and quiet faster (minimum value of rise time t_{rt} and From these figures, it is clearly observed that the transient stabilization performance PSO-FPIDC and TLBO-FPIDC is better than PSO-PID and TLBO-PID and all of the controllers are better performance than CPSS. The dynamic performance presented in Table 6 and Table 7. It is clear appeared that PSO-FPIDC has lower peak over-shoot O_{sh}/U_{sh} under shoot (U_{sh} , short settling time t_{st} and rise time t_{rt} . So we can say that PSO-FPIDC is the best dynamic performance with respect to other controllers.

11. CONCLUSION

Stability of electric power system can be lost either by lack of synchronizing torque, or due to lack of damping torque oscillatory in due to oscillation caused by external perturbations. In this paper Particle Swarm Optimization Fuzzy PID controller PSO-FPIDC used to enhance the dynamic stability of Single Machine Infinite Busbar system

Khaled Eltag received the B.Sc. degree in Electrical and Electronic Engineering, Faculty of Engineering Sciences from Omdurman Islamic University (OIU), Khartoum, Sudan, in 2003 and his M.S. degree in Electrical Power Engineering, Faculty of Engineering and Architecture from University of Khartoum, Khartoum, Sudan, in 2012. He is studying for a Ph.D. degree

from 2016 in Control Science and Engineering with the School of Automation, from Nanjing University of Science and Technology, P. R. China. He was Lecturer at the Department of Electrical and Electronic Engineering from 2006 to 2016, Omdurman Islamic University (OIU), Khartoum, Sudan. His research interests include fuzzy system, non-linear system control, adaptive control, and electrical power system stability and control.

Muhammad Shamrooz Aslam received his B.Sc. and M.S. degree in Electronics and Electrical Engineering from COMSATS University, Abbottabad and Attock campus, Pakistan, in 2009 and 2013 respectively. He is studying for a Ph.D. degree from 2015 in Control Science and Engineering with the School of Automation, from Nanjing University of Science and Technology, P. R. China. He was Lecturer at the Department of Electrical Engineering from 2010 to 2015, COMSATS University, Attock campus. His research interests include fuzzy system, time-delay systems, non-linear systems and network control system, etc.

Rizwan Ullah obtained his B.S. in Electronics Engineering in 2009 and his M.S. in Electrical Engineering in 2013 from COMSATS University Abbottabad and Attock campus Pakistan respectively. He worked as Lecturer at COMSATS University Attock campus from 2013 to 2017. Currently he is pursuing toward a Ph.D degree at School of Automation, Nanjing University of Science and Technology China. His research interest includes control system design, nonlinear output regulation, fuzzy control and electromechanical system control.
