**Abstract** The potential application of high-capacity  $\text{Sn}_4\text{P}_3$  anode for potassium-ion batteries (PIBs) is hindered by the poor cycle stability mainly rooted from the huge volume changes upon cycling and low electronic conductivity. To address the above issues, sandwich-like structured  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  was designed and synthesized as anode material for PIBs. As a result,  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  presents superior cycle stability (retains a capacity of  $103.2 \text{ mAh}\cdot\text{g}^{-1}$  even after 300 cycles at  $1000 \text{ mA}\cdot\text{g}^{-1}$ ) and rate capability (delivers  $60.7 \text{ mAh}\cdot\text{g}^{-1}$  at high current density of  $2000 \text{ mA}\cdot\text{g}^{-1}$ ). The excellent electrochemical performance of sandwich-like structured  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  is originated from the synergistic effect between  $\text{Sn}_4\text{P}_3$  and  $\text{Ti}_3\text{C}_2\text{T}_x$ , where  $\text{Ti}_3\text{C}_2\text{T}_x$  acts as a conductive matrix to facilitate electron transfer and buffer the volume change of  $\text{Sn}_4\text{P}_3$  particles upon cycling, while  $\text{Sn}_4\text{P}_3$  serves as pillars to prevent the collapse and stacking of  $\text{Ti}_3\text{C}_2\text{T}_x$  sheets. Moreover, significant capacitive contribution is

demonstrated as a major contributor to the excellent rate capability.

**Keywords**  $\text{Sn}_4\text{P}_3$ ;  $\text{Ti}_3\text{C}_2\text{T}_x$ ; Anode material; Potassium-ion battery

## 1 Introduction

With the spread of portable electronic devices and the boom in the new energy vehicle industry, there is an urgent need to develop energy storage devices with high performance and low cost [1, 2]. Due to the high energy density and good cycle stability, lithium-ion batteries (LIBs) have accounted for most of the consumer battery market. However, the limited resources of lithium ore and its uneven global distribution limit its use in large-scale energy storage applications [3]. Considering the high natural abundance of potassium (2.09 wt%, while 0.0017 wt% for Li) and the similar energy storage mechanism to that of LIBs, potassium-ion batteries (PIBs) have attracted much attention as a promising alternative to LIBs [4–6]. However, the larger  $\text{K}^+$  radius (0.138 nm) leads to slow reaction kinetics and larger volume changes of active material during cycling [7]. Up to now, the development of PIBs is still in its infancy and electrode materials with high capacity and good cycling stability are yet to be developed [8, 9].

Graphite is the most extensively used anode material with excellent electrical conductivity, and large layer spacing (3.4 nm) [10]. Unfortunately, the practical application of graphite anode material remains challenging mainly due to its low capacity. In this regards, alloy-based materials are potential alternatives due to their high capacity. Among the alloy-based materials,  $\text{Sn}_4\text{P}_3$ , which

possesses a high theoretical capacity of  $612 \text{ mAh}\cdot\text{g}^{-1}$  and synergistic benefits of Sn and P, is deemed as the most promising anode for PIBs [11–13]. However, the low electronic conductivity ( $30.7 \text{ S}\cdot\text{cm}^{-1}$ ) and huge volume changes during charge/discharge process lead to sluggish reaction kinetics and poor cycling stability [12, 14–16]. To tackle these limitations, an effective strategy is to combine  $\text{Sn}_4\text{P}_3$  with highly conductive skeleton [16–18]. For instance, Zhang et al. [12] prepared  $\text{Sn}_4\text{P}_3/\text{C}$  composite via ball-milling technique and studied it as anode for PIBs, which delivers a reversible capacity of  $384.8 \text{ mAh}\cdot\text{g}^{-1}$  at  $50 \text{ mA}\cdot\text{g}^{-1}$ . However, the  $\text{Sn}_4\text{P}_3$ -based composites prepared by the ball-milling method are poor in terms of cycle stability [14, 19, 20]. The capacity retention of  $\text{Sn}_4\text{P}_3/\text{C}$  composite is only  $\sim 6.6\%$  after 120 cycles. Therefore, further efforts are still needed to achieve high capacity, long-term cycle stability as well as high-rate performance.

$\text{Ti}_3\text{C}_2\text{T}_x$ , as a new member of two-dimensional layered material family, has shown unique advantages in the field of energy storage due to its layered structure, superior electrical conductivity ( $6500 \text{ S}\cdot\text{cm}^{-1}$ ), and low diffusion barrier [21–25]. Intensive study has been performed on the use of  $\text{Ti}_3\text{C}_2\text{T}_x$  as electrode materials for energy storage batteries, such as hybrid  $\text{Ti}_3\text{C}_2/\text{NiCoP}$  for sodium ion batteries [26],  $\text{Ti}_3\text{C}_2/\text{Si}$  composite for LIBs [27], and  $\text{MoS}_2/\text{MXene}$  hybrids for PIBs [28]. Yet, incorporating MXene with high capacity  $\text{Sn}_4\text{P}_3$  anode has rarely been tried.

Herein, we prepared a novel sandwich-like structured  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite, which has rarely been reported before, via a solvothermal reaction followed by phosphorization process. Electrochemical study demonstrates that  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  owns superior cycle stability and rate capability, which benefits from the synergistic effect between  $\text{Sn}_4\text{P}_3$  and  $\text{Ti}_3\text{C}_2\text{T}_x$ . In  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite,  $\text{Ti}_3\text{C}_2\text{T}_x$  acts as a conductive matrix to facilitate electron transfer and buffer the volume change of  $\text{Sn}_4\text{P}_3$  particles during charge/discharge, while  $\text{Sn}_4\text{P}_3$  serves as pillars to prevent the collapse and stacking of  $\text{Ti}_3\text{C}_2\text{T}_x$  sheets.

## 2 Experimental

Except for  $\text{Ti}_3\text{C}_2\text{T}_x$  powder was purchased from Jilin 11 Technology Co., Ltd, all other materials used in this experiment were purchased from Shanghai Macklin Biochemical Co., Ltd.

### 2.1 Synthesis of $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$

In a typical preparation,  $\text{SnCl}_2\cdot 2\text{H}_2\text{O}$  and  $\text{Ti}_3\text{C}_2\text{T}_x$  powder with different mass ratios of 1:0.5, 1:1 and 1:2 were added into ethanol solution, followed by an ultrasonic treatment process for 1 h. Afterward, 20 ml NaOH solution with concentration of  $0.2 \text{ mol}\cdot\text{L}^{-1}$  was added into the above mixture and stirred for 0.5 h. The solution was subsequently transferred into Teflon-lined stainless-steel autoclave and reacted at  $180 \text{ }^\circ\text{C}$  for 10 h. The obtained  $\text{SnO}/\text{Ti}_3\text{C}_2\text{T}_x$  powder was then washed with deionized water and collected by freeze-drying. To get  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$ , appropriate  $\text{NaH}_2\text{PO}_2\cdot\text{H}_2\text{O}$  and  $\text{SnO}/\text{Ti}_3\text{C}_2\text{T}_x$  powder were

**Fig. 2** XRD patterns of  $\text{Ti}_3\text{C}_2\text{T}_x$ ,  $\text{SnO}/\text{Ti}_3\text{C}_2\text{T}_x$ , and  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$

**Fig. 1** Schematic illustration of synthesis process of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite

**Fig. 3** SEM images of **a** Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> and **b** Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>; **c** TEM image of Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>; **d** HRTEM images and (inset) FFT pattern of Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>; **e** TEM image and corresponding elemental mappings of Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>

annealed in tube furnace in Ar atmosphere with temperature of 280 °C for 0.5 h. Electrochemical results in Fig. S1 show that the Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> sample with an initial SnCl<sub>2</sub>·2H<sub>2</sub>O to Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> mass ratio of 1:1 possesses the optimal performance. Therefore, it was selected for further research. As a control, bare Sn<sub>4</sub>P<sub>3</sub> was prepared in the same process without adding Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> powder.

## 2.2 Material characterizations

The crystal structure, composition and morphology of the samples were investigated by X-ray diffraction (XRD, Rigaku, Ultima IV) with Cu K $\alpha$  radiation, X-ray photoelectron spectroscopy (XPS, Thermo Scientific K-Alpha), scanning electron microscope (SEM, Zeiss Sigma 300), and transmission electron microscope (TEM, JEOL JEM 2100F), respectively.

## 2.3 Electrochemical characterizations

The electrode was fabricated by coating the mixed slurry of 80 wt% of the as-prepared Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> or bare Sn<sub>4</sub>P<sub>3</sub>, 10 wt% carbon black, and 10 wt% polyvinylidene fluoride (PVDF) binder in N-methyl pyrrolidone (NMP) onto the copper foil. The electrodes were then vacuum-dried at 85 °C for 12 h and cut into disks with loading of  $\sim 0.8 \text{ mg}\cdot\text{cm}^{-2}$ . Electrochemical performance was measured with CR2032-type coin cells, where K foil works as counter/reference electrode and KPF<sub>6</sub> in ethylene carbonate/diethyl carbonate works as electrolyte. Galvanostatic charge–discharge (GCD) was tested on a Land CT2001A battery testing system. Cyclic voltammograms (CV) and electrochemical impedance spectroscopy (EIS) tests were carried out at CHI660e electrochemistry workstation. CV was conducted in a voltage range of 0.01–2.00 V. EIS was tested over a frequency range from

10 MHz to 100 kHz by applying an alternating current (AC) signal of 5 mV.

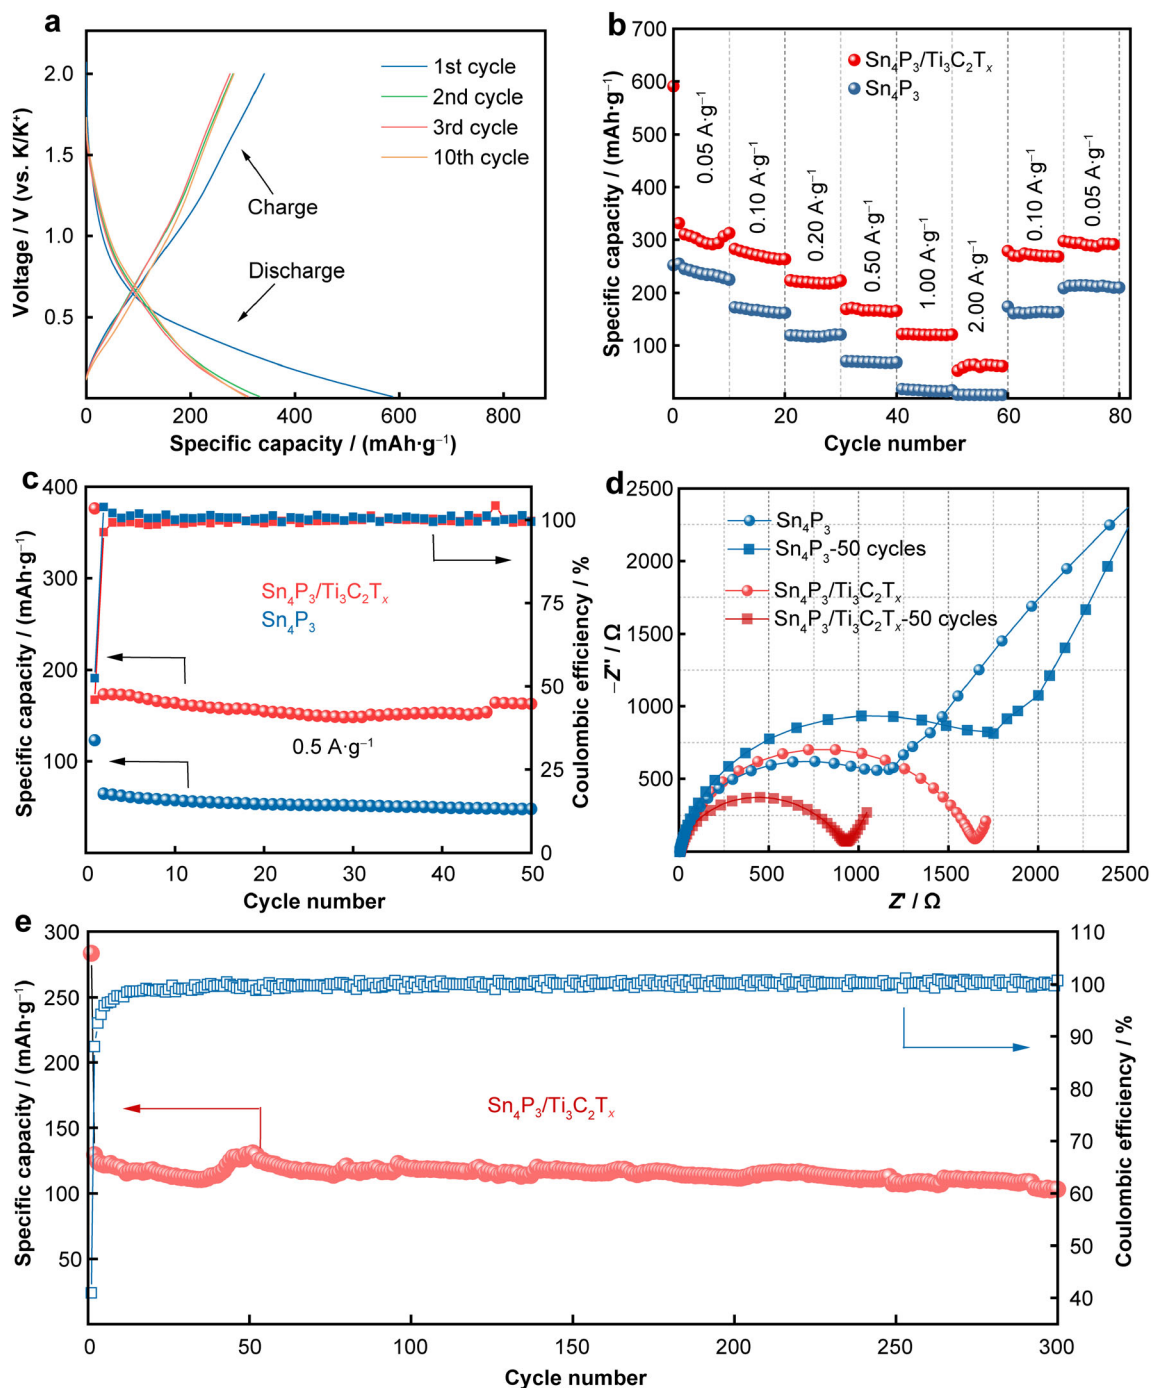

### 3 Results and discussion

Figure 1 illustrates the synthesis process of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite. Firstly,  $\text{SnO}$  nanoparticles are loaded on the surface of  $\text{Ti}_3\text{C}_2\text{T}_x$  by a hydrothermal reaction. Afterward, in situ phosphorization reaction is conducted in a tube furnace and the  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite material is finally obtained.

The crystal structures of the materials were investigated by XRD. As shown in Fig. 2, the defined peaks at  $\sim 6.46^\circ$  could be assigned to (002) planes of titanium carbide, which agrees well with previous reports [29–31]. In the XRD pattern of final product of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$ , the diffraction peaks locating at  $\sim 27.7^\circ$ ,  $28.8^\circ$ ,  $30.3^\circ$ ,  $31.4^\circ$ ,  $44.5^\circ$ ,  $45.7^\circ$  and  $56.5^\circ$  are indexed as (104), (015), (0012), (107), (0114), (110) and (027) planes of rhombohedral  $\text{Sn}_4\text{P}_3$  (JCPDS No. 73-1820) respectively [15, 32], while the extra peaks can be attributed to  $\text{Ti}_3\text{C}_2\text{T}_x$ , indicating the successful coupling of  $\text{Sn}_4\text{P}_3$  and  $\text{Ti}_3\text{C}_2\text{T}_x$ .

Morphology of pristine  $\text{Ti}_3\text{C}_2\text{T}_x$  and the product of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  was investigated by SEM. Figure 3a shows the SEM image of  $\text{Ti}_3\text{C}_2\text{T}_x$ , in which a typical

accordion-like and well-aligned layered structure is clearly observed. The layered structure still maintains even after a long time of hydrothermal reaction and high-temperature phosphating process (Fig. 3b), suggesting the excellent structural stability of  $\text{Ti}_3\text{C}_2\text{T}_x$ . Moreover,  $\text{Sn}_4\text{P}_3$  nanoparticles are evenly distributed on the surface of  $\text{Ti}_3\text{C}_2\text{T}_x$  sheets, thus forming a sandwich-like structure (Fig. S2). In this structure,  $\text{Sn}_4\text{P}_3$  nanoparticles can act as pillars to prevent the collapse and stacking of  $\text{Ti}_3\text{C}_2\text{T}_x$  sheets, while the  $\text{Ti}_3\text{C}_2\text{T}_x$  sheets could provide a good conductive matrix and unblocked channels for electron transmission and  $\text{K}^+$  transfer, respectively, thereby achieving synergistic effect. TEM images were collected to reveal the structural and morphological details of  $\text{Ti}_3\text{C}_2\text{T}_x$  and  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite. As shown in Fig. 3c, obvious multilayer structure is observed for matrix. Figure 3d shows high-resolution transmission electron microscope (HRTEM) image and fast Fourier transformation (FFT) pattern of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$ , clear fringes with lattice spacing of 0.320 and 0.204 nm are observed, corresponding to (104) and (0114) planes of  $\text{Sn}_4\text{P}_3$ , respectively. HRTEM images in Fig. S3 reveal the expansion of the interlayer spacing from  $\text{Ti}_3\text{C}_2\text{T}_x$  to  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$ , which is mainly caused by the insertion of cations between the layers during synthesis process. Elemental mappings in Fig. 3e suggest

**Fig. 5** **a** Selected galvanostatic charge/discharge profiles of Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> at current density of 50 mA·g<sup>-1</sup>; **b** rate capability and **c** cycle performance of Sn<sub>4</sub>P<sub>3</sub> and Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> electrodes at 500 mA·g<sup>-1</sup>; **d** Nyquist plots of Sn<sub>4</sub>P<sub>3</sub> and Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> electrodes before and after 50 cycles; **e** long-term cycling performance of Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> electrode at 1 A·g<sup>-1</sup> (working voltage of 0.01–2.00 V)

that Sn<sub>4</sub>P<sub>3</sub> particles are homogeneously distributed on the matrix of Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>.

The chemical states of different elements in Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> composite were analyzed by XPS. Figure 4a shows the full-scan spectrum of Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> sample, demonstrating the existence of Ti, C, Sn, P, O and F. Figure 4b–f exhibits the high-resolution XPS spectra of Ti

2p, C 1s, Sn 3d, P 2p and O 1s, respectively. Ti 2p spectrum in Fig. 4b can be deconvoluted into four species of Ti<sup>2+</sup>, Ti<sup>3+</sup>, Ti–C and Ti–O, which is consistent with the previous literatures [33, 34]. Figure 4c displays four peaks at ~ 281.5, 284.7, 286.4 and 288.8 eV, which are assigned to the characteristic bonds of C–Ti, C–C, C–O and C=O, respectively. In terms of Sn 3d spectrum in Fig. 4d, the

peak at  $\sim 487.1$  eV is resulted from spin-orbital splitting photoelectrons of Sn, which is relevant to the Sn–P bond of  $\text{Sn}_4\text{P}_3$  phase. While another peak situated at  $\sim 485.1$  eV corresponds to  $\text{Sn}^0$  [35, 36]. As displayed in Fig. 4e, P 2p spectrum is divided into three peaks. Two peaks locating at  $\sim 129.6$  and  $130.3$  eV are related to typical P  $2p_{3/2}$  and P  $2p_{1/3}$ , corresponding to P–Sn bond of  $\text{Sn}_4\text{P}_3$  phase. While the small peak at  $\sim 133.3$  eV is attributed to P–O bond, indicating that the oxidized phosphate species remain on the surface of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$ . For O 1s spectrum in Fig. 4f, the peaks at  $\sim 529.4$ ,  $531.3$ ,  $532.1$  and  $533.0$  eV correspond to O–Ti, O=C, O–C and O–P, respectively. XPS results further illustrate that  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite was synthesized successfully.

To evaluate potassium storage properties, the  $\text{Sn}_4\text{P}_3$  and  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  were investigated by using CR2032-type coin cells, in which potassium foils were used as counter/reference electrodes. CV was firstly carried out at a scan rate of  $0.1 \text{ mV}\cdot\text{s}^{-1}$  with the potential window between 0.01 and 2.00 V. As shown in Fig. S4, a broad peak between 0.01 and 1.00 V is observed in the initial cathodic scan, which is derived from the potassiation reaction to form K-P and K-Sn phases as well as the formation of solid electrolyte interphase (SEI). In the following anodic scan, a weak peak centered at 0.8 V can be observed, corresponding to the de-potassiation process. The second and third CV curves overlap with each other, indicating the good reversibility of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  during charge and discharge.

Figure 5a shows the selected charge/discharge profiles at current density of  $50 \text{ mA}\cdot\text{g}^{-1}$  between 0.01 and 2.00 V (vs.  $\text{K}/\text{K}^+$ ). In the first cycle,  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode delivers a discharge and charge capacity of 586.6 and 340.9  $\text{mAh}\cdot\text{g}^{-1}$ , respectively, corresponding to an initial Coulombic efficiency of  $\sim 58\%$ . The irreversible loss of the initial capacity is mainly resulted from the formation of SEI films on the surface of the electrode material [37]. In the subsequent cycles,  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  gives stable capacity of  $\sim 304.8 \text{ mAh}\cdot\text{g}^{-1}$  and the Coulombic efficiency reaches up to  $> 98\%$ . Compared with  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite electrode, the capacity of  $\text{Sn}_4\text{P}_3$  electrode is only  $\sim 228 \text{ mAh}\cdot\text{g}^{-1}$  under the same current density.

Rate capability of pure  $\text{Sn}_4\text{P}_3$  and  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite was measured at various current densities ranging from 0.05 to  $2.00 \text{ A}\cdot\text{g}^{-1}$ . As shown in Fig. 5b,  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite delivers reversible capacities of 304.8, 270.7, 220.3, 167.4, 120.8 and  $60.7 \text{ mAh}\cdot\text{g}^{-1}$  at current densities of 0.05, 0.10, 0.20, 0.50, 1.00 and  $2.00 \text{ A}\cdot\text{g}^{-1}$ , respectively, which is obviously superior to that of pure  $\text{Sn}_4\text{P}_3$ . In addition, most of the capacity is recovered ( $\sim 292.5 \text{ mAh}\cdot\text{g}^{-1}$ ) when the current density returns to  $0.05 \text{ A}\cdot\text{g}^{-1}$ , demonstrating that the electrode is able to accommodate the massive current changes in application.

It is worth mentioning that the rate capability of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  presented in our work surpasses Sn-based anodes reported previously (Fig. S5) [38–40], which is mainly due to that the accordion-like skeleton with good conductivity allows easy penetration of electrolyte and transfer of electrons.

Cycling performance of the bare  $\text{Sn}_4\text{P}_3$  and  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  was compared at  $0.5 \text{ A}\cdot\text{g}^{-1}$  in Fig. 5c.  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode delivers a charge capacity of  $173.1 \text{ mAh}\cdot\text{g}^{-1}$  for the first cycle, which is significantly higher than  $64.5 \text{ mAh}\cdot\text{g}^{-1}$  obtained from  $\text{Sn}_4\text{P}_3$  electrode. Moreover, the  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode retains a high capacity of  $162.6 \text{ mAh}\cdot\text{g}^{-1}$  with capacity retention of  $\sim 94\%$  after 50 cycles. By contrast, the capacity of bare  $\text{Sn}_4\text{P}_3$  electrode decays quickly with cycling and only  $48.2 \text{ mAh}\cdot\text{g}^{-1}$  is remained at 50th cycle. Nyquist plots were collected and exhibited in Fig. 5d. It can be clearly seen that the charge transfer resistance of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  decreases with cycling, due to the activation of electrode [14]. Whereas the  $\text{Sn}_4\text{P}_3$  electrode shows larger impedance after 50 cycles, which is attributed to the pulverization and exfoliation of  $\text{Sn}_4\text{P}_3$  particles (details will be presented by ex-situ SEM shown in Fig. 6). The smaller resistance well accounts for the excellent cycling stability and rate capability of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite. Long-term cycle performance of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  was further evaluated at a current density of  $1.0 \text{ A}\cdot\text{g}^{-1}$ . As displayed in Fig. 5e,  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode still delivers a specific capacity of  $103.2 \text{ mAh}\cdot\text{g}^{-1}$  even after 300 cycles, which is  $\sim 81\%$  of its initial reversible capacity.

To further explore the reason for the largely improved potassium storage performance of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  composite, morphology of the electrodes before and after cycling was studied by SEM. As shown in Fig. 6a, c, both  $\text{Sn}_4\text{P}_3$  and  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrodes present flat surface before cycling. While after 50 cycles, cracks are clearly observed in  $\text{Sn}_4\text{P}_3$  electrode (Fig. 6b). In sharp contrast, the surface of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode remains flat and intact, except for some fibers from glass fiber separator (Fig. 6d). These results reveal that the introduction of  $\text{Ti}_3\text{C}_2\text{T}_x$  could effectively alleviate the stress induced by volume change during charge/discharge, thus enabling the integrity of electrode and fast transfer of electrons, which contribute greatly to the electrochemical performance (Fig. 6e, f).

Reaction kinetics of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode was analyzed by CV. As shown in Fig. 7a, the intensity of peaks increases with the scanning rate increasing from 0.2 to  $1.0 \text{ mV}\cdot\text{s}^{-1}$ . However, the CV curves always maintain a similar shape, which means that  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode owns good response ability under fast scanning rate. Diffusion and capacitive contribution are qualitatively determined by the relationship between current ( $i$ ) and scan rate ( $v$ ) according to the following equations:

**Fig. 6** SEM images of **a** initial and **b** 50 charge/discharge cycled Sn<sub>4</sub>P<sub>3</sub> electrodes; **c** initial and **d** 50 charge/discharge cycled Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> electrodes (insets being digital photos of each electrode); Schematic illustration of potassiation process and de-potassiation of **e** Sn<sub>4</sub>P<sub>3</sub> and **f** Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>

$$i = av^b \quad (1)$$

$$\lg i = b \lg v + \lg a \quad (2)$$

where  $a$  and  $b$  are adjustable constants, and the value of  $b$  can be confirmed by the slope of  $\lg i$ - $\lg v$  curves. When the value of  $b$  is close to 0.5 or 1.0, the reaction process is diffusion control or capacitance control, respectively. As depicted in Fig. 7b, the calculated  $b$  values of the anodic and cathodic peaks are 0.86 and 0.75 respectively, which implies that the electrochemical reaction process is controlled by both diffusion and capacitance behavior. The ratios of diffusion and capacitive contribution are obtained based on the following equation:

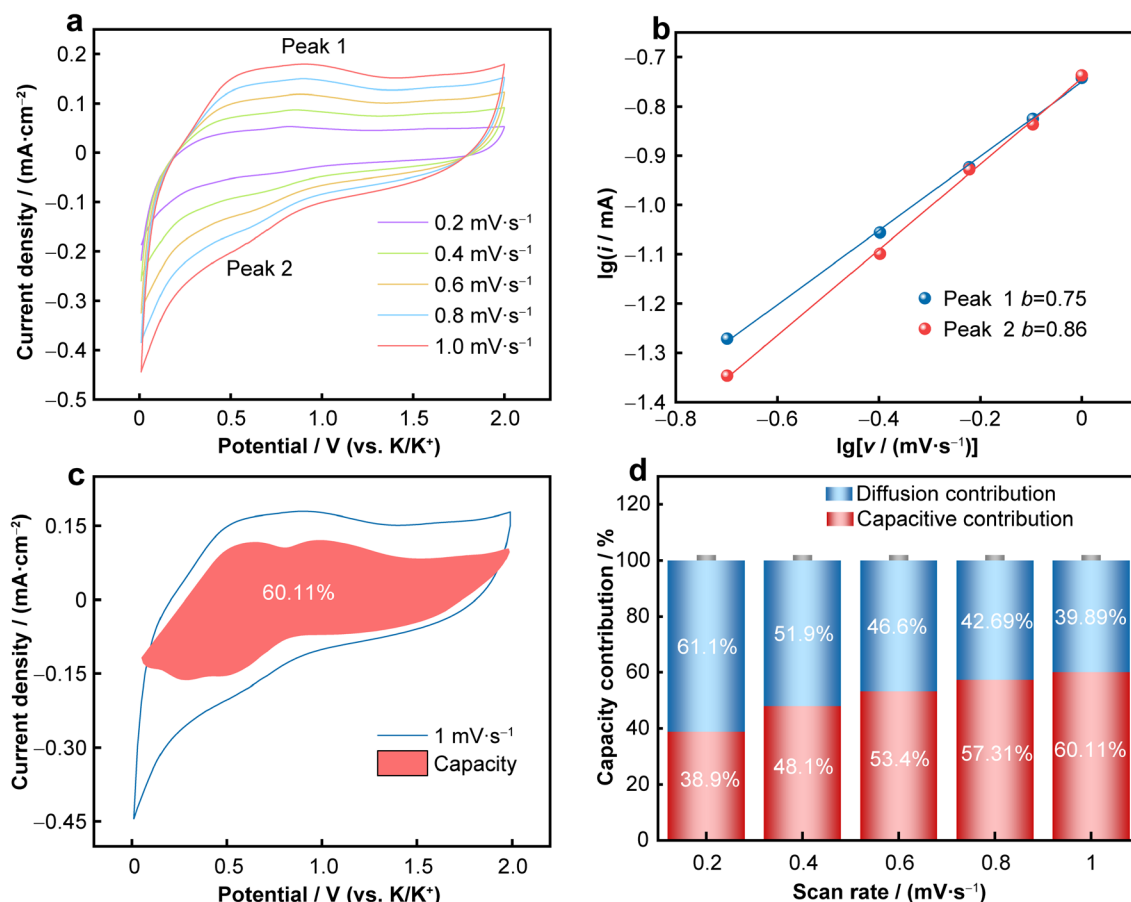

$$i(v) = k_1v + k_2v^{1/2} \quad (3)$$

where  $k_1v$  and  $k_2v^{1/2}$  correspond to the contributions of the capacitive effect and diffusion-controlled process, respectively. As illustrated in Figs. 7c, d and S6, the ratio of

capacitive contribution gradually increases with the increase of scanning rate. This demonstrates that the electrochemical reaction process of the Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> electrode is mainly controlled by the capacitive behavior at high rate, which is beneficial for rate performance.

## 4 Conclusion

In summary, sandwich-like structured Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> composite was synthesized via solvothermal reaction along with low-temperature phosphating process. The electrochemical properties of Sn<sub>4</sub>P<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> composite is evaluated as anode for PIBs. The introduction of the highly conductive Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> matrix not only provides channels for fast electron transfer, but also alleviates the volume change of Sn<sub>4</sub>P<sub>3</sub> upon charge/discharge. Moreover, the loading of Sn<sub>4</sub>P<sub>3</sub> nanoparticles serves as pillars to prevent Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>

**Fig. 7** a CV curves of  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  electrode at various scan rates; b  $\lg i$ - $\lg v$  plots obtained from corresponding CV curves; c capacitive charge storage contribution at  $1 \text{ mV}\cdot\text{s}^{-1}$ ; d separation of contributions from capacitive- and diffusion-controlled capacities at various scan rates

sheets from collapse or stack. Owing to the synergistic effect between the two components,  $\text{Sn}_4\text{P}_3/\text{Ti}_3\text{C}_2\text{T}_x$  exhibits significantly improved electrochemical performance than  $\text{Sn}_4\text{P}_3$ , which can be ranked as a high-performance anode material for PIBs.
