**Abstract** The objective of this study was to investigate the performance of employing solar photo-Fenton to treat petroleum wastewater from Sohar oil refinery, evaluate this process by a central composite design with response surface methodology and evaluate the relationship among operating variables such as pH, H<sub>2</sub>O<sub>2</sub> dosage, Fe<sup>+2</sup> dosage, and reaction time to identify the optimum operating conditions. Quadratic models proved to be significant with very low probabilities (<0.0001) for the following responses: total organic carbon (TOC) and chemical oxygen demand (COD). The optimum conditions were H<sub>2</sub>O<sub>2</sub> dosage (850 mg L<sup>-1</sup>), Fe<sup>+2</sup> dosage (60 mg L<sup>-1</sup>), pH (3.68) and reaction time (127 min) in this method. The experimental results of the maximum TOC and COD removal rates corresponded good with the predictions, which were 59.3 and 74.7 %, respectively. This method achieved well degradation efficiencies for TOC and COD and reduced the treatment time comparing with the previous work.

**Keywords** Photo-Fenton · Petroleum wastewater · Chemical oxygen demand (COD) · Total organic carbon (TOC)

## Introduction

Large amount of water was used in the petroleum refinery activity and, consequently, significant volumes of wastewater was generated. Recently, one of the major problems facing industrialized nations was contamination of the environment by hazardous chemicals. A wide range of pollutant compounds were detected in petroleum waste water in Sohar Oil Refinery. So, the elimination of these chemicals from petroleum wastewater was presently one of the most important aspects of pollution control in Oman.

Advanced oxidation processes (AOPs) had capability of rapid degradation of recalcitrant pollutants in the aquatic environment. They had shown high efficiency to remove the organic compounds from effluents even when they are present at low concentrations (Silva et al. 2015; Philipopoulos and Pouloupoulos 2003; Masomboon et al. 2010; Paz et al. 2013). Remediation of hazardous substances was attributed to hydroxyl radical, which exhibited reactivity toward organic (Hermosilla et al. 2009).

AOPs might be used in wastewater treatment for reduction of overall organic content (COD), color, odor and specific pollutant or sludge treatment (Tony et al. 2012). There were two Fenton reactions; the standard Fenton reaction between Fe<sup>+2</sup> ions and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and the Fenton-like reaction between Fe<sup>+3</sup> ions and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) (Yeh et al. 2008). Fenton reaction under light such as sunlight or UV was the so-called photo-Fenton and more hydroxyl radicals (·OH) were generated (Torrades et al. 2004).

The Fenton process has three major steps (Eqs. 1–4) (Silva et al. 2015; Krutzler and Bauer 1999);

(a) Production of hydroxyl radicals (·OH).

<sup>2</sup> Caledonian College of Engineering, Seeb, Oman

(b) Reproduction of  $\text{Fe}^{+2}$  ions by energy.

(c) Degradation of the organic compounds by hydroxyl radicals ( $\cdot\text{OH}$ ).

The reactions with hydroxyl radicals could be triggered by several ways depending on the structure of the organic compounds; electron transfer, abstraction of hydrogen atom, and electrophilic (a molecule with a tendency to react with other molecules containing a donatable pair of electrons) addition to compounds containing unsaturated bonds (Silva et al. 2015; Legrini et al. 1993). The major drawbacks of Fenton process were iron complexation by carboxylic intermediates. But these complexes could be photo-activated by photo-Fenton process and additional hydrogen peroxide ( $\text{HO}^\cdot$ ) generation (Amor et al. 2015). Therefore, solar photo-Fenton experiments were applied to treat petroleum wastewater.

Solar photo-Fenton is based on using solar radiation to increase production of hydroxyl radicals ( $\cdot\text{OH}$ ) and photoactive complexes through the Fenton process (Amor et al. 2015; Fernandes et al. 2014; Lucas et al. 2012; Pignatello et al. 2006). Using solar energy in AOPs could reduce processing costs and make it more affordable for commercial use (Amor et al. 2015).

Several previous studies reported the enhanced oxidation of contaminants by the photo-Fenton process, for example, Kositzia et al. (2004) showed the solar photo-Fenton process was more efficient for synthetic municipal wastewater in comparison to the photocatalyst of  $\text{TiO}_2$  process because  $\text{H}_2\text{O}_2$  slowly decomposed into oxygen and water. In addition, the abundance, lack of toxicity and ease of removal from water made  $\text{Fe}^{2+}$  the most commonly used transition metal for Fenton process (Badawy and Ali 2006).

Moreover, this process had less amount of harmful by-products in comparison to other AOPs. (Demorais and Zamora 2005). The amounts of reagents depended on the concentrations of degradable materials present in the wastewater which were a fundamental factor. But using an efficient radiation system and a suitable design of the photo-Fenton reactor would improve process performance and reduced reagents consumption (Rossiter et al. 2013). Coelho et al. (2006) reported that the maximum DOC removal attained was 87 % by the photo-Fenton process from petroleum refineries wastewater (sourwater). Previous

work by Tony et al. (2012) used the photo-Fenton method for the oil-refinery wastewater achieved approximately 50 % COD removal in the optimum concentrations; pH 3,  $\text{H}_2\text{O}_2$  (400 mg  $\text{L}^{-1}$ ), and  $\text{Fe}^{2+}$  (40 mg  $\text{L}^{-1}$ ). Rossiter et al. (2013) showed that the 53 % COD removal was achieved by the solar photo-Fenton process from petroleum wastewater.

The main aims for this study are as follows:

- To investigate the performance of solar photo-Fenton in petroleum wastewater treatment.
- To evaluate the performance of employing the proposed method by a central composite design (CCD) with response surface methodology (RSM) to degradation of TOC and COD from the petroleum wastewater.
- To evaluate the statistical relationships among operating variables (such as pH,  $\text{H}_2\text{O}_2$  dosage,  $\text{Fe}^{+2}$  dosage, and reaction time) and the responses, which COD and TOC removal efficiencies were selected as the responses for optimization.
- To determine the optimum operational conditions of the proposed method.
- To compare the proposed method with the previous works.

## Materials and methods

### Wastewater characteristic

The physicochemical characteristics of the petroleum wastewater from Sohar oil refinery (SOR) were summarized in Table 1. Samples of the petroleum waste water were collected on different days. Samples were transferred to the laboratory and stored under refrigeration (4 °C) until use. Samples were characterized before the experiments to obtain their chemical and physical properties. The petroleum wastewater characterization was determined by the quantification of pH, total organic compounds (TOC) and chemical oxygen demand (COD) according to the standard methods for the examination of waste water methodology.

### Materials

Samples of the petroleum wastewater were collected from Sohar oil refinery, Oman. Hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) [35 % (v/v)] and Iron sulfate hydrate ( $\text{FeO}_{12}\text{S}_3$ ) (which was used as source of  $\text{Fe}^{+2}$  in the photo-Fenton treatment) are supplied by EMPROVE. Exp. They were used for the solar photo-Fenton process to degradation of TOC and COD. Sulfuric acid (95–97 %) and sodium hydroxide (50 %) were used to adjust the pH to the desired values.

**Table 1** Characteristics of the petroleum wastewater from Sohar oil refinery (SOR)

| No. | Parameter                 | Range of concentrations in petroleum wastewater | Average | The standard discharge limit |
|-----|---------------------------|---|---------|------------------------------|
| 1   | pH                        | 6–8   | 7       | 6–9                          |
| 2   | Conductivity (Micro S/cm) | 2600–3950                                       | 3275    | 2000–2700                    |
| 3   | TDS (ppm)                 | 1200–1500                                       | 1350    | 1500–2000                    |
| 4   | TOC (ppm)                 | 220–265   | 243     | 50–75                        |
| 5   | COD (ppm)                 | 550–1600  | 1075    | 150–200                      |

**Analytical procedure**

A Shimadzu TOC analyzer (LCSH/CSN) was used to measure the TOC for each sample. Chemical oxygen demand (COD) was measured by COD photometer (manufactured by CHEMetrics). COD was estimated before and after treatment. Before each analysis, samples were filtered by filter papers (0.22 um Millipore Durapore membrane, 40 Ashless, Diameter 150 mm). Solar ultraviolet radiation (UV) was measured by a global UV radiometer (KIPP & ZONEN).

**Experimental procedure**

A sketch of the solar photo-Fenton processes was shown in Fig. 1. It consisted of a glass recirculation tank (5 L), which was subjected to stirring to maintain a well-mixed solution during the experiments, connected to the tubular solar reactor [four tubes (50 cm length × 2 cm inner diameter × 0.1 cm thickness)]. The tubular photo reactor operated at a UV-index from 8 to 11 according to exposure category was very high as shown in Fig. 2.

The UV-Index is calculated as follow:

Take the output from the UV-E radiometer according to ISO 17166:1999/CIE S007/E-1998. Transform the output voltage to W/m<sup>2</sup> with the instruments sensitivity. Equation (5) allows calculating the amount of UV intensity received on any surface in the same position with regard to the sun by UV-Index (UVI):

$$UVI = R (W/m^2) \times 40 (m^2/W) \tag{5}$$

where, UVI is the UV-Index, *R* is the reading (*R*) in UV radiometer by (W/m<sup>2</sup>) unit.

The solution was circulated through the reactor at a flow rate of about 1.5 L/min by means of a peristaltic pump. The Fenton reagents were added in a glass recirculation tank during this process.

The pH for petroleum wastewater samples was used between 2 and 6. Several sets of experiments were carried out according to a central composite design (CCD) with response surface methodology (RSM) to determine the COD and TOC removal efficiency under the optimum operational conditions.

At the end of each run, in order to avoid iron precipitation in the reactor, the samples were withdrawn and then kept them at rest for 30 min. By increasing the pH of sample to (8), the major iron ion was precipitated because the removal efficiency of organics by Fenton stopped (Salem et al. 2013).

Tekin et al. (2006) showed that the treatment efficiency of Fenton ceased when the pH was equal to or greater than 7 because the generation of hydroxyl radicals was reduced due to lack of presence of free iron ions. The excess of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) was removed by adding MnO<sub>2</sub> and the suspension was stirred until the formation O<sub>2</sub> was finished (no bubbles on surface) (Herrmann and Verlag 1996). The presence of H<sub>2</sub>O<sub>2</sub> normally provokes accurate COD values (Amor et al. 2015).

**Results and discussion**

**Experimental design and the analysis of variance (ANOVA)**

Central composite design and response surface methodology were employed in the statistical design of the experiments, data analysis, explaining the optimal conditions of the independent variables and assessment of the relationships among four significant independent variables, which were pH, H<sub>2</sub>O<sub>2</sub> dosage, Fe<sup>+2</sup> dosage, and reaction time as shown in Table 2.

The adequacy of the proposed model for degradation of COD and TOC of the petroleum wastewaters by Fenton’s reagent was evaluated at optimum conditions. Each independent variable was varied over three levels according to face centered CCD as −1, 0, and +1, respectively at the determined ranges based on a set of preliminary experiments. The total number of experiments conducted for the four factors according to Eq. (6)

$$\text{No. of Experiments} = 2^k + 2k + 6 \tag{6}$$

where, *k* was the number of factors.

The design consisted of 2<sup>*k*</sup> factorial points augmented by 2*k* axial points and six replications for a center point. In this work, the total number of experiments

Table 2 Central composite design (CCD) independent variables

| The factors  | Level of value |      |      |
|--|----------------|------|------|
|  | -1             | 0    | 1    |
| pH   | 2              | 4    | 6    |
| H <sub>2</sub> O <sub>2</sub> (g L <sup>-1</sup> ) | 1              | 0.75 | 0.5  |
| Fe <sup>+2</sup> (g L <sup>-1</sup> )              | 0.01           | 0.04 | 0.08 |
| Reaction time (min)                                | 60             | 120  | 180  |

conducted for the four factors were 30 with 16 factorial points, eight axial points and six replications to assess the pure error and got a good estimate. The COD and TOC removal were the dependent variables (responses) during this process. Performance was evaluated by

analyzing the COD and TOC removal efficiencies as shown in Table 3.

The behavior of the system was explained through an empirical second-order polynomial model, as shown in Eq. (7): (Montgomery 2008)

$$Y = \beta_0 + \sum_{j=1}^k \beta_j X_j + \sum_{j=1}^k \beta_{jj} X_j^2 + \sum_i \sum_{<j=2}^k \beta_{ij} X_i X_j + e_i \tag{7}$$

where,  $Y$  was the response,  $X_i$  and  $X_j$  were the variables,  $\beta$  was the regression coefficient,  $k$  was the number of factors studied and optimize in the experiment,  $e_i$  was the random error.

The analysis of variance (ANOVA) was used for graphical analysis of data to obtain the interaction between

**Table 3** Responses values for different experiment conditions

| Run | Factors |   |  |             | Responses          |                    |
|-----|---------|---|--|-------------|--------------------|--------------------|
|     | A, pH   | B, H <sub>2</sub> O <sub>2</sub> (g L <sup>-1</sup> ) | C, Fe <sup>+2</sup> (g L <sup>-1</sup> ) | D, RT (min) | 1, TOC removal (%) | 2, COD removal (%) |

the process variables and the responses. The quality of the fit polynomial model was expressed by coefficient of determination (*R*<sup>2</sup>). Model terms were evaluated by the *P* value (probability) with 95 % confidence level.

The analysis of variance (ANOVA) for TOC and COD removal were represented in Table 4. All the response surface quadratic models for parameters in this table were significant at the 5 % confidence level since the *P* values were less than 0.05. The correlation coefficients (*R*<sup>2</sup>) for the TOC and COD removal rates were 0.983 and 0.986, respectively, which were greater than 0.80, the cut-off for a model with good fit. A high coefficient (*R*<sup>2</sup>) value ensured a satisfactory adjustment of the quadratic model to the experimental data and illustrated good agreement between the calculated and observed results and showed that a

desirable and reasonable agreement with the adjusted *R*<sup>2</sup> (Salem et al. 2013).

If the model terms had the *P* value (probability) more than 0.05, they were considered limited influence. So, they had to be excluded from the study to improve the models. The model of TOC and COD removal were considered significant using the *F* test at 5 % significant level (*P* < 0.05). The “adequate precision” (AP) ratio values higher than four were desirable and confirm that the predicted models could be used to navigate the space defined by the central composite design (CCD) (Noordin et al. 2004). The “adequate precision” (AP) ratio of the models in this study was adequate, which varied between 30.74 and 35.28.

**Normal probability**

Design Expert 6.0.7 software program (a statistical software package from Stat-Ease Inc) provided plots of normal probability of the studentized residuals and diagnostics to evaluate the models and confirmed that they provided an adequate approximation of the real system. As shown in Fig. 3, the normal probability plots for the studentized residuals for TOC and COD removal efficiency predicted that if the residuals followed a normal distribution, the points fell along a straight line for each case.

However, some scattering were expected even with normal data; thus, the data could be considered to be normally distributed in the responses of certain models. Empirical relationships among the variables and COD and TOC removal efficiencies after excluding insignificant coefficients were presented by the following polynomial Eqs. (8, 9):

$$\begin{aligned} \text{TOC removal (\%)} = & 57.36 - 4.1A + 6.1B + 2.5C \\ & + 1.4D - 13.4A^2 - 7.5B^2 - 7.7C^2 \\ & - 7.4D^2 + 2.1BC \end{aligned} \tag{8}$$

$$\begin{aligned} \text{COD removal (\%)} = & 71.6 - 5.5A + 7.5B + 5.4C \\ & + 3D - 16.4A^2 - 10.4B^2 - 5.9C^2 \\ & - 10.9D^2 + 2.3BC \end{aligned} \tag{9}$$

where, *A*, *B*, *C* and *D* were model terms that represent coded factors of pH, H<sub>2</sub>O<sub>2</sub> dosage, Fe<sup>+2</sup> dosage, and reaction time, respectively. Final equations in terms of actual factors were presented by the following Eqs. (10, 11):

$$\begin{aligned} \text{TOC removal (\%)} = & -113.9 + 24.7\text{pH} + 193\text{H}_2\text{O}_2 \\ & + 455.4\text{Fe}^{+2} + 0.5\text{RT} - 3.3\text{pH}^2 \\ & - 119.6(\text{H}_2\text{O}_2)^2 - 6266.4(\text{Fe}^{+2})^2 \\ & - 0.0002\text{RT}^2 + 241.4(\text{H}_2\text{O}_2)(\text{Fe}^{+2}) \end{aligned} \tag{10}$$

### Three-dimensional plots of the regression and optimization process

As shown in Figs. 4 and 5, the response surfaces plots were created by Design Expert 6.0.7 provided a three-dimensional view of the TOC and COD removals surface over the independent variables. The main factors of this process that improved the TOC and COD removal were H<sub>2</sub>O<sub>2</sub> dosages, Fe<sup>+2</sup> dosages. Using the high dosages of Fenton reagents to degradation of organic matter was attributed to

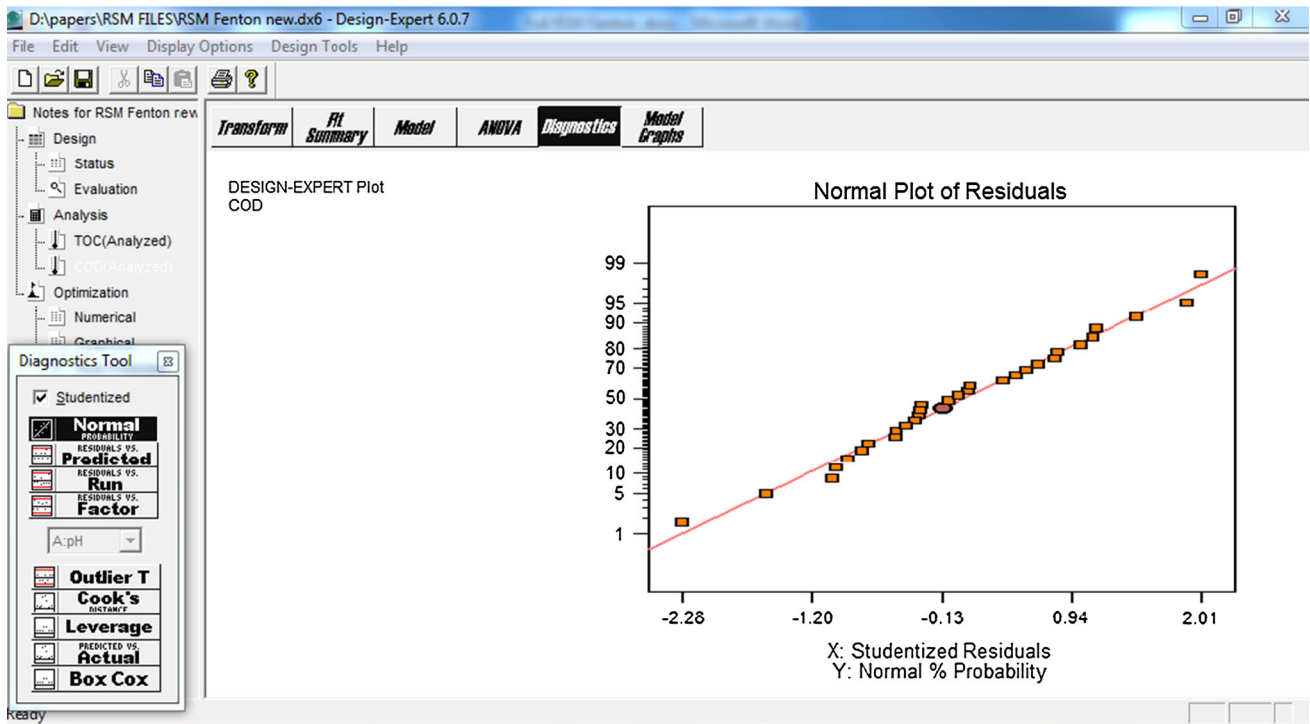

the nature of petroleum wastewater which had the recalcitrant pollutants and then decreased the process efficiency due to chloride ions, which were able to react with hydroxyl radicals, producing less reactive radicals (Maciel et al. 2004). So the concentration of Fenton's reagent employed must be enough to overcome the restrictions.

Design Expert 6.0.7 was used to determine optimization of removal efficiency for TOC and COD. The pH, H<sub>2</sub>O<sub>2</sub> dosage, Fe<sup>+2</sup> dosages, and reaction time were chosen as "within" the range in the software optimization step. The responses (TOC and COD removals) were defined as "maximum" to achieve the highest performance. The program combined individual desirability into a single number and then search to optimize this function based on the response goal.

Figure 4d showed the COD removal by Fenton oxidation and the corresponding pH variation over time under

(a)

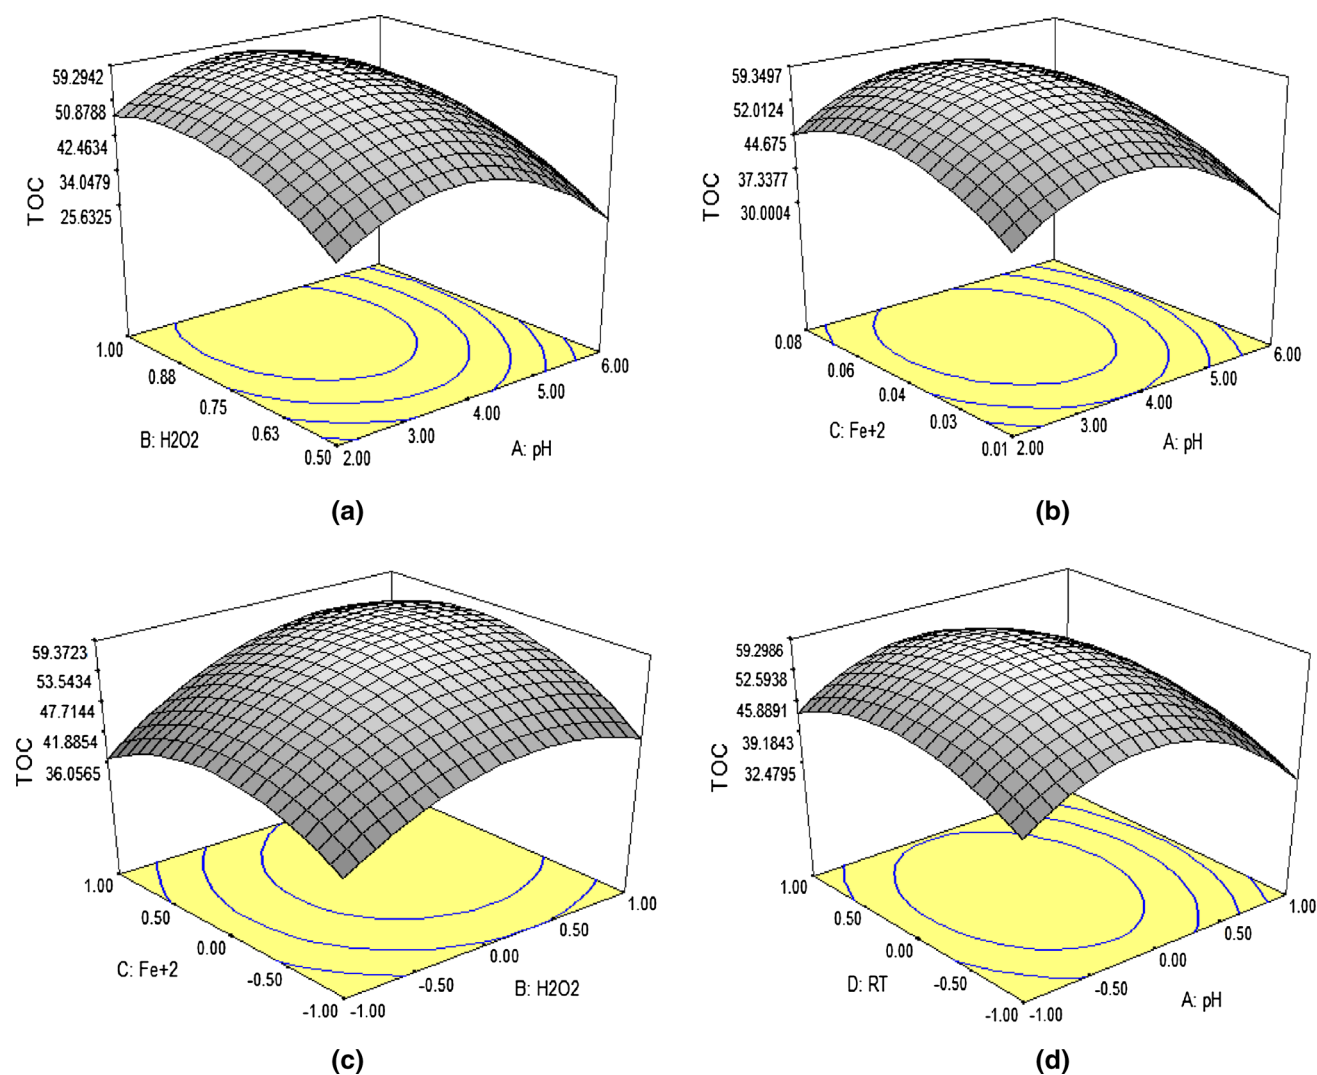

(b)

**Fig. 3** Design expert plot, Normal probability plot of the studentized residuals for **a** TOC and **b** COD removal

the optimal conditions a rapid degradation up to 90 min followed a slow degradation. The rapid degradation was attributed to high hydroxyl radical (OH) concentrations

which it exhibited reactivity toward organic compounds as a result of amounts of  $Fe^{2+}$  catalyst in solution that reacts with  $H_2O_2$ . At the second stage, after 90 min,  $Fe^{2+}$  ions

**Fig. 4** Response surface models for TOC

were decreased and the excess of H<sub>2</sub>O<sub>2</sub> reacted with hydroxyl radical ( $\cdot\text{OH}$ ) in result to slower rate of production hydroxyl radical ( $\cdot\text{OH}$ ) (Luna et al. 2013).

As shown in Table 5, the model under optimized operational conditions, which were H<sub>2</sub>O<sub>2</sub> dosage (850 mg L<sup>-1</sup>), Fe<sup>2+</sup> dosage (60 mg L<sup>-1</sup>), pH (3.68) and reaction time (127 min), predicted TOC and COD removal rates approximately 59.3 and 74.7 %, respectively and the desirability function was 0.988.

To confirm these results, an additional experiment under optimized operational conditions was carried out which was revealing agreement with the predicted responses. The near connection between the experimental and the predicted results supported the reliability of the model.

The results of this research were compared with those of other works that treated the wastewater by using the photo-Fenton method, for example, Rossiter et al. (2013) showed

that polycyclic aromatic hydrocarbons and aromaticity removal of approximately 92.7 and 96.2 %, respectively, from petroleum-extraction wastewater were obtained by a solar photo-Fenton like process after 420 min and solar photo-Fenton process achieved 53 % COD removal. Tony et al. (2012) obtained 50 % COD removal after using (H<sub>2</sub>O<sub>2</sub>/Fe<sup>2+</sup>/UV) method under optimal conditions; pH 3, H<sub>2</sub>O<sub>2</sub>/Fe<sup>2+</sup> ratio 10 while the current study revealed that the solar photo-Fenton process in an AOP was more efficient in the petroleum wastewater treatment, achieving a 74.7 % COD removal at conditions; pH 3.68, H<sub>2</sub>O<sub>2</sub>/Fe<sup>2+</sup> ratio 14.

The maximum of COD removal at pH 3.68 agreed with the results found in the literature for other wastewaters treated by Fenton process, for example, Mohajeri et al. (2010) reported that at pH 3 the COD and color removals were 58 and 78 %, respectively within 120 min of reaction

**Fig. 5** Response surface models for COD

**Table 5** Maximum TOC and COD removal efficiencies for model response and verification experiments under optimum conditions [H<sub>2</sub>O<sub>2</sub> dosage (850 mg L<sup>-1</sup>), Fe<sup>+2</sup> dosage (60 mg L<sup>-1</sup>), pH (3.68) and reaction time (127 min)]

|                 | Selected solution | Lab experiments | Error % |
|-----------------|-------------------|-----------------|---------|
| TOC removal (%) | 59.3              | 62              | 4.3     |
| COD removal (%) | 74.7              | 72              | 3.6     |
| Desirability    | 0.988             | –               | –       |

time. Results of Ertugay and Acar (2013) indicated that the highest COD removal was determined 50.7 % at pH 3.

The complexity of intermediate compounds during the reaction and the high initial reaction rate made the study of

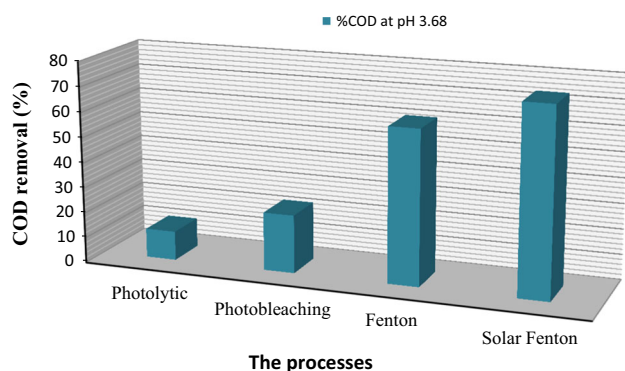

Fenton process very difficult in industrial wastewater (Lucas and Peres 2009). Comparing this work with the previous works was summarized in the Table 6.

**Evaluation of the photolytic process**

To evaluate the photolytic effect on the COD reduction, the photocatalytic experiments were carried out under sunlight; the tubular photo reactor operated at a UV-index of 9 (according to Exposure category was very high) as shown in Fig. 6. The results revealed that the photolytic process was less efficient in the petroleum wastewater treatment, achieving a 11.5 % COD removal at pH 3.68 after 180 min of solar irradiation.

**Table 6** Overview of work done in the area of photo-Fenton application in recent years

| No. | The process   | Wastewater type  | Removed material       | Max. removal efficiency (%) | References                |

**Fig. 6** COD removal from petroleum wastewater under different processes

### The combined action of solar radiation and H<sub>2</sub>O<sub>2</sub>

After the evaluation of the photolytic process, some experiments were carried out by adding 0.85 g L<sup>-1</sup> Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) [35 % (v/v)], which was the

optimum H<sub>2</sub>O<sub>2</sub> concentration as determined previously, to evaluate the effect of the Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) with solar radiation. The results revealed that 23 % of COD was removed within 180 min at pH 3.68. The degradation was attributed to the photochemical cleavage of H<sub>2</sub>O<sub>2</sub> by solar light absorption resulting to increase rate of production hydroxyl radical (·OH) (Oliveira et al. 2012; Parson 2004).

### Evaluation of the Fenton process

To evaluate the performance of employing the Fenton process in the absence of solar irradiation to treat petroleum wastewater, The dark Fenton experiments were carried out with adding 0.85 g L<sup>-1</sup> Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) [35 % (v/v)] and 0.06 g L<sup>-1</sup> Iron sulfate hydrate (FeO<sub>12</sub>S<sub>3</sub>) at pH 3.68.

Results of this process indicated that the COD removal was decreased to 61 % at pH 3.68 after 180 min, due to the lower generation of hydroxyl radical (·OH).

## Conclusion

The general results of this work indicated that the solar photo-Fenton was a practical method to treat petroleum wastewaters, allowing achieved well removal of TOC and COD. Quadratic models for the following two responses proved to be significant with very low probabilities ( $<0.0001$ ): Chemical oxygen demand (COD), total organic carbon (TOC). The obtained optimum conditions included  $\text{H}_2\text{O}_2$  dosage ( $0.85 \text{ g L}^{-1}$ ),  $\text{Fe}^{+2}$  dosage ( $0.06 \text{ g L}^{-1}$ ), pH (3.68) and reaction time (127 min). TOC and COD removal rates were 59.3 and 74.7 %, respectively. The predictions correspond well with experimental results. The current study revealed that the solar photo-Fenton process in an AOP was well efficient in the petroleum wastewater treatment, achieving a 74.7 % COD removal at conditions; pH = 3.68,  $\text{H}_2\text{O}_2/\text{Fe}^{+2}$  ratio = 14.
