SPECIAL ISSUE: Innovative Electrode Materials for Supercapacitors

Recent advancements in metal organic framework based electrodes for supercapacitors

Yujie Zhao[1], Jinzhang Liu[1*], Michael Horn[2], Nunzio Motta[2], Mingjun Hu[1] and Yan Li[1*]

ABSTRACT   Metal organic frameworks (MOFs) are considered as very promising candidates to build electrodes for electrochemical energy storage devices such as lithium ion batteries, fuel cells and supercapacitors, due to their diverse structure, adjustable aperture, large specific surface area and abundant active sites. Supercapacitor has been widely investigated in the past decades. Of critical importance in these devices is the electrode active materials, and this application has been intensively studied with the development of novel nanomaterials. In this review we summarize recent reports on MOFs as electrode materials for supercapacitors. Specifically, the synthesis of MOF materials for supercapacitor electrodes and their performance in electrochemical energy storage are discussed. We aim to include supercapacitor electrode materials related to MOFs, such as carbon, metal and composite materials. It is proposed that MOFs play an important role in the development of a new generation of supercapacitor electrode materials. Finally, we discuss the current challenges in the field of supercapacitors, with a view towards how to address these challenges with the future development of MOFs and their derivatives.

Keywords: metal organic frameworks (MOFs), electrochemistry, supercapacitors, electrode, derivative

INTRODUCTION

Supercapacitors, taking advantage of the properties of conventional capacitors and ionic batteries, have attracted widespread research focus in the past four decades. Their unique properties, including high power density, fast charge/discharge rate, long cycle life and environmental friendliness, make supercapacitors attractive devices for a variety of applications in energy storage such as electronic communications, the emergent electric transportation industry and aerospace [1–10].

The energy storage mechanism of supercapacitors can be generally classified into two categories: electric double-layer capacitance (EDLC) and pseudocapacitance [1,11–14]. EDLC is based on the physical adsorption and desorption of ions at the interface between an electrolyte and electrode. Normally, carbon-based materials (activated carbon, graphene, carbon nanotubes, etc.) with good conductivity and high specific surface area are used as electrode active materials [15,16]. Pseudocapacitance stores charge *via* reversible redox reactions between an electrode and electrolyte. Electrode active materials can be metal oxides (NiO_x, RuO_2, MnO_2, etc.) or conductive polymers (polyaniline, polypyrrole, etc.) [17–20]. In general, the specific capacitance of these materials is higher than that of the carbon-based materials in EDLC supercapacitor electrodes, owing to the chemical adsorption and desorption of H^+ in acidic electrolyte or alkali metal cations in alkaline media [21–25]. However, there is debate on the classification of pseudocapacitive materials, because some exhibit distinct redox peaks in cyclic voltammetry (CV) loops as ionic battery materials do. In most cases, the capacitance of pseudocapacitive nanostructures is contributed by both Faradaic and EDLC. The EDLC contribution becomes more dominant with reducing the size, i.e., increasing the specific surface area, of pseudocapacitive nanocrystals.

In order to develop high-performance active materials for supercapacitor electrodes, several key aspects are focused on. Desirable characteristics in these materials include adjustable pore size distribution, high accessible specific surface area (SSA), high electrochemical activity and good electrical conductivity [26–28]. Carbon-based materials are superior in terms of SSA, electrical con-

ductivity and chemical stability, but along with relative lower specific capacitance and energy density [4,16,29]. For pseudocapacitive materials, relatively lower surface area and inferior porosity suppress the dissociation of active component and ions from electrolyte and slow the electron or ion transfer, resulting in a limited power density. Furthermore, the redox reaction of the electrode material cannot be fully completed in the rapid charge and discharge process, which leads to a lower rate capability [22,23]. The development of new materials for improved supercapacitor electrodes requires maintaining the above desirable characteristics, while addressing the limitations of currently used materials.

Metal organic frameworks (MOFs) are a new category of porous materials consisting of metal ions or ion clusters and organic ligands connected through coordination bonds, auxiliary hydrogen bonds, metallic bonding, or van der Waals force interaction. It is also known as "coordination polymer" formed *via* self-assembly, resulting in a highly structured infinite network [30–33]. When compared with traditional porous materials, MOFs have the advantages of diverse scaffold structure, adjustable pore size, large SSA, and an abundance of active sites. Currently, MOFs have been widely used in gas adsorption and separation, catalysis, drug delivery, imaging, and sensors [31,34,35]. Interest in this new type of porous material is growing rapidly as its potential application in many fields is becoming realized. In recent years, MOFs and their derivatives have also been applied in the field of electrochemical energy storage, such as in lithium-ion batteries, fuel cells and supercapacitors. However, since MOFs are crystalline due to their ordered network constructed through coordination bonds between ligands and the metal center, the skeleton of MOFs is flexible and the electrical conductivity is generally inferior to carbonaceous electrode materials. Consequently, MOFs and MOF derivatives with good stability and high conductivity are highly urgent in the development of supercapacitor electrodes [36–42].

This paper reviews the recent research progress of MOFs and their derivatives in the application of supercapacitors. The content is divided into three sections. (1) MOFs applied in supercapacitors. (2) MOF derivatives including porous carbons, metal oxides and metal sulfides that maintain the characteristics of MOFs, and are used to make supercapacitor electrodes. (3) MOF composite electrodes. This section discusses the composite materials based on MOFs or their derivatives for supercapacitor electrodes. Finally, we summarize the current problems of MOFs and their derivatives in the field of supercapacitor

electrodes as well as their possible direction for development in the future.

MOFs DIRECTLY USED AS SUPERCAPACITOR ELECTRODES

MOFs show strong potential for advanced supercapacitor electrodes due to their inherent properties including large SSA, adjustable pore size and abundance of active sites [43]. The large SSA of MOFs can increase the contact area between MOFs electrode and electrolyte, which further improves the specific capacitance. Furthermore, the adjustable pore size can ensure the fast transport of electrons and electrolyte ions while the abundant active sites can promote the pseudocapacitance. The specific capacitance was calculated by CV and galvanostatic charge/discharge (GCD). The areal capacitance is used to represent the capacitance per square centimetre apparent area of activated material. What is more, improving the specific capacitance of electrode materials is an effective way to get high energy density because the energy density (E) of supercapacitor is proportional to the specific capacitance (C) according to the equation [44]: $E=CV^2/2$, where E is the energy, C is the capacitance, and V is the voltage. Apart from the capacitance, widening voltage window is the other approach to improve the energy density, while it is related to the type of electrolyte.

Lee *et al.* [45] synthesised Co-based MOFs at 100°C using cobalt nitrate and terephtalic acid for supercapacitors. A Co-MOF film with a uniform thickness of 5 μm was constructed by MOF nanoparticles ranging from 50 to 100 nm (Fig. 1a). The Co-MOF film delivered a maximum pseudocapacitance of 206.76 F g^{-1} in LiOH electrolyte at 0.6 A g^{-1} (Fig. 1c), together with strong cycling stability, retaining 98.5% of the initial capacity after 1000 cycles. This is attributed to the fine crystalline structure of the MOF, stable in various electrolytes, as evidenced by XRD (Fig. 1b). In LiOH electrolyte, the organic ligands of the MOF can be continuously separated and recombined with the central metal ions, resulting in a high cyclic stability for Co-MOF films. The stability of Co-MOFs is on a par with Co-oxide materials [46,47]. It was noteworthy that the change of the highly crystalline phase of CoO was observed in LiCl and KCl electrolytes. Among Co-based oxides, only Co_3O_4 has good capacitance properties, so the appearance of CoO leads to lower capacitance in LiCl and KCl electrolyte (Fig. 1c).

Following the above report, Lee *et al.* [48] further studied the effects of organic linkers with different molecular lengths on producing Co-MOFs with different
Figure 1 (a) Scanning electron microscopy (SEM) top and cross-sectional view (inset) of Co-MOF films; (b) X-ray diffraction (XRD) patterns of Co-MOF films after 1000 cycles in different electrolytes; (c) CV curves of Co-MOF film in different electrolytes. pore sizes and surface areas (Fig. 2a–c). Typically, three organic linkers, 1,4-benzenedicarboxylic acid (H$_2$BDC), 2,6-naphthalenedicarboxylc (H$_2$NPC) and 4,4-biphenyldicarboxylic (H$_2$BPDC) with increased molecular lengths were used. These Co-MOF films were produced using blade coating technique as previously employed by Lee *et al.* [45]. They found that a longer organic linker produced larger pores and larger surface area, compared with a shorter linker. The best performance was obtained from the MOF employing the longest linker, H$_2$BPDC. This material was denoted as Co-BPDC and possessed a pore mode distribution about 78.96 nm, and an associated SSA of 138.35 m^2 g^{-1}. The Co-BPDC displayed a

maximum capacitive performance of 179.2 F g^{-1} (Fig. 2d) at a scanning rate of 10 mV s^{-1}. In addition, the loss of capacitance was 6% after 1000 cycles for these Co-BPDC based electrodes (Fig. 2e), and the structure was not obviously altered (Fig. 2f). These results indicate that the larger effective surface area and pore diameter have a positive effect on the capacitance of the supercapacitors constructed by these MOFs.

Miles *et al.* [49] also prepared cobalt based MOFs. The electrically insulating Co-MOF-71 1,4-benzenedicarboxylate in *N,N*-dimethylformamide [Co(BDC)DMF] was obtained by reacting a cobalt salt with the organic ligand H$_2$BDC. This work demonstrated how this 3-D co-

ordination polymer may be induced to become electrochemically active *via* "conformal transformation", whereby the chemical structure is altered without significant modification of the crystalline shape. Co^{2+} acts as the central metal ion reacting with OH^- to produce $Co(OH)_2$ in a strong alkaline environment, and the product possesses a more highly porous structure, suitable for psuedocapacitance (Fig. 3). In this report the Co-MOF-71 was able to be fully transformed in alkaline electrolytes and displayed modest specific capacitances at pH≥11.

Ni-based MOFs also attract great interest due to their unique structure as well as Co-MOFs reviewed above. Yang *et al.* [50] reported a high performance Ni-MOF-24 prepared by nickel chloride and *p*-benzodicarboxylic acid (PTA). The capacitance of Ni-MOF-24 was up to 1,127 F g^{-1} in 6 mol L^{-1} KOH electrolyte at the current density of 0.5 A g^{-1}. Meanwhile, a good cyclic stability of over 90% capacitance retention was obtained after 3,000 cycles. The excellent performance was ascribed to the layered structure and favorable exposed facets of the as-prepared Ni-based MOF material.

Yan *et al.* [51] prepared Ni-MOFs (Fig. 4) with a novel accordion morphology using the same organic ligand and metal ions as in Yang's report [50]. In a conventional three-electrode test cell, a specific capacitance of 988 F g^{-1} was achieved for Ni-MOF in 3 mol L^{-1} KOH at 1.4 A g^{-1}. Notably, the capacitance retention was 96.5% after 5,000 cycles, which is close to that of some carbon electrode materials. Furthermore, a flexible solid-state asymmetric supercapacitor (ASC) was assembled with Ni-MOF as the positive electrode, and an activated carbon as negative electrode. The capacitance of the ASC was 230 mF cm^{-2} at a current density of 1 mA cm^{-2} (Fig. 5a). After 5,000 cycles, the capacitance retention was 92.8% (Fig. 5b). These Ni-MOFs showed excellent specific capacitance and stability, which was higher than that of previous metal compounds [52]. Jiao *et al.* [53] also reported the electrochemical properties of obtained Ni-MOF with a similar method. The specific capacitance of the Ni-MOF at a current density of 0.5 A g^{-1} was found to be 948 F g^{-1}
Figure 5 (a) The specific capacitance of the supercapacitor device at different current densities. The inset image is a photograph of the device. [51], Copyright 2016, the Royal Society of Chemistry.

with 3 mol L^{-1} KOH+0.1 mol L^{-1} KOH in $K_4Fe(CN)_6$ as the electrolyte.

Xu *et al.* [54] synthesized a high performance rod-like Ni-MOF *via* hydrothermal method using nickel nitrate and the organic ligand, salicylic acid. The SSA of the obtained Ni-MOF reached 186.8 m² g^{-1}. The specific capacitance of Ni-MOF was calculated to be 1,698 F g^{-1} in 6 mol L^{-1} KOH electrolyte at 1 A g^{-1} using a three-elec-

trode test cell. The excellent capacitance was ascribed to the high SSA, suitable pore size distribution and fast charge mobility of the rod-like Ni-MOF. In addition, the capacitance retention rate was 94.8% after 1000 cycles. Furthermore, the specific capacitance of an ASC fabricated from Ni-MOF and graphene electrodes was 166 F g^{-1} at 1 A g^{-1}.

Currently, Ni-MOFs generate a lot of research interest given their promising electrochemical performance. As described above, they are applied as supercapacitor electrode materials and can display high specific capacitances and exceptional retention rates, justifying their position as a material of interest for this purpose.

Worrall *et al.* [55] prepared zeolitic imidazolate frameworks (ZIFs) with imidazole (IM), benzimidazole (bIM), methyl imidazole (mIM) and ethyl imidazole (eIM) as organic ligands *via* electrochemical coating (Fig. 6). Of the variations reported, the ZIF-67 electrodes displayed the highest areal capacitance of 10.45 mF cm^{-2} at a scanning rate of 10 mV s^{-1}. In addition, the electrical conductivity of ZIF-67 was also observed to be the best out of the reported MOFs and graphene complexes, as can be seen from Table 1.

Yang *et al.* [56] produced layered Co-MOFs using cobalt nitrate and PTA organic ligands (Fig. 7), and tested these in 5 mol L^{-1} KOH electrolyte. A resulting capaci-

ZIF-14	3.21	8,320
ZIF-67	2.77	21

tance of 2,564 F g^{-1} was achieved at 1 A g^{-1}, and a considerable 1,164 F g^{-1} was maintained as the current density was increased to 20 A g^{-1}. Compared with the Ni-MOFs reported above, this type of Co-MOF demonstrated relatively similar cyclic stability, achieving 95.8% after 3,000 cycles. The authors found that there was enough space for electrolyte storage within the large interlayer distance of Co-MOFs, which endowed them with more facile OH$^-$ intercalation and deintercalation, improving the capacitance of the MOFs (Fig. 7c). The prepared Co-MOFs also displayed excellent conductivity due to the conductive network, as shown in Fig. 7d. The conductive network structure (allowing fast and efficient electron transfer) as well as the diffusion enabling geometries (the layered structure and nanosheet morphology) are key aspects that enhanced the capacitive

performance of Co-MOFs in this study.

Sheberla et al. [57] constructed honeycomb-like structured Ni-MOFs (Fig. 8) using nickel and 2,3,6,7,10,11-hexaiminotriphenylene (H_6HITP). The Ni-MOFs showed excellent EDLC performance in an ionic liquid electrolyte. The specific capacitance of Ni-MOFs was measured to be 111 F g^{-1} in 1 mol L^{-1} TEABF$_4$/CAN electrolyte at 0.05 A g^{-1}, together with a surface area normalized capacitance of 18 μF cm^{-2}, which is greater than that of most carbon materials. The improved EDLC of Ni-MOFs is due to the appropriate pore diameter and good electrical conductivity. Evidently, the columnar voids and the electrolyte ions were consistent with the appropriate pore sizes (1.5 nm) of the Ni-MOFs [58]. In addition, the presence of conjugated π bonds is also a key aspect that increases the charge mobility and further enhances the electrical conductivity of the as-prepared Ni-MOFs [31].

MOF DERIVED ELECTRODE MATERIALS

Porous carbons
MOFs have been widely investigated over the past two decades given their intrinsic ordered porous network structure, high SSA and uniform pore size distribution.

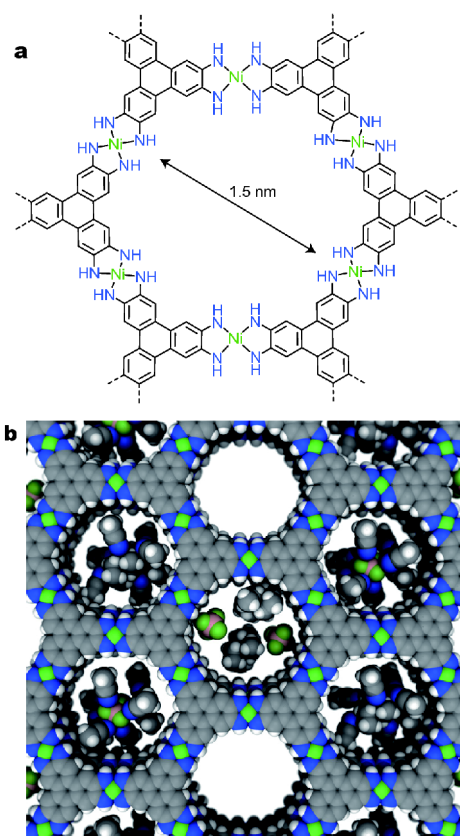

Figure 8 (a) Molecular structure of Ni-MOF; (b) relative size of pores, electrolyte Et$_4$N$^+$ and BF$_4^-$, and acetonitrile solvent molecules shown in a space-filling diagram of idealized Ni-MOF. However, there remain limitations in the application of MOFs. Specifically, MOFs possess relatively poor thermal and chemical stability, due to their skeleton structure. This drawback greatly limits the application of MOFs in industrial settings, and remains a key challenge to be addressed. To address the issue, many researchers have focused on the design and synthesis of highly stable MOFs. Alternatively, some researchers began to consider how the poor stability and easy decomposition characteristics of MOFs may be improved. As a result, versatile nanoporous carbon materials have been prepared through the carbonisation of MOFs, and these are able to retain high SSA and uniform pore size distribution. The high SSA and uniform pore size distribution are beneficial to the contact between the electrode and the electrolyte as well as accelerating the transfer of electrolyte ions, potentially enhancing the EDLC. There are two common methods for preparing porous carbon materials by MOFs. (1) The MOF backbones act as a carbon source,
Figure 9 (a) Schematic structure of MOF-5 and IRMOF-3; (b) XRD patterns; (c, d) SEM images of CIRMOF-3-950; (e, f) SEM images of CMOF-5-950. Reproduced with permission from Ref. [59], Copyright 2014, American Chemical Society.

and are directly carbonized to obtain carbon material. (2) Adding other carbon sources to MOFs, and then carbonizing them into carbon material.

MOFs used as carbon sources

Generally, porous carbon materials can be obtained by carbonization and acid treating of MOFs because the low boiling point of metal center, such as Zn (i.e., 907°C) in Zn-MOF.

Nitrogen doped isoreticular MOFs (IRMOF-3) (Fig. 9a) were prepared *via* solvothermal approaches using zinc nitrate and H_2DBC, 2-aminobenzene-1,4,-dicarboxylate by Jeon *et al.* [59]. The material was subsequently converted to a nitrogenous porous carbon IRMOF, or carbonized IRMOF (CIRMOF), by thermal treatment. Compared to MOF-5 which was subjected to similar thermal carbonization treatment, denoted as CMOF, the SSA of the precursor MOF-5 and IRMOF-3 was found to be 1,305 and 1,221 $m^2 g^{-1}$, respectively. The effect of carbonization temperature was investigated for the MOFs (Fig. 9c–f). The ideal temperature was found to be 950°C considering capacitive performance. After carbonization, the SSA of carbonized MOFs at 950°C (CMOFs-950) and carbonized isoreticular MOFs at 950°C (CIRMOF-3-950) was 572 and 553 $m^2 g^{-1}$, respectively. It can be seen from the XRD pattern that the characteristic peaks of ZnO disappeared after 950°C annealing, proving that the

CMOFs-950 and CIRMOF-3-950 are carbon materials with no metal ions (Fig. 9b). A specific capacitance of 239 F g^{-1} was achieved for CIRMOF-3-950 in 1 mol L^{-1} H_2SO_4 electrolyte at 0.5 A g^{-1}, which was greater than that of CMOFs-950 (24 F g^{-1}). It is worth noting that the specific capacitance of CIRMOF-3-950 was not significantly reduced after 10,000 cycles, indicating the good cyclic and structural stability. Furthermore, when comparing the two carbon materials, the nitrogen-doped CIRMOF-3-950 material displayed higher capacitive performance, suggesting that the N-doping has a positive effect.

Hao *et al.* [60] prepared nitrogen doped porous carbon materials through carbonizing and activating ZIF-11. Specifically, ammonium hydroxide was added to the reactant solution when synthesizing ZIF-11. The SSA of the prepared nitrogen doped porous carbon material was as high as 2,188 $m^2 g^{-1}$. This material also exhibited a high specific capacitance of 307 F g^{-1} in 1 mol L^{-1} H_2SO_4 electrolyte at 1 A g^{-1}.

Yang *et al.* [61] also obtained porous carbon materials by carbonizing Zn-MOF that was prepared through the reaction of zinc nitrate and different organic ligands, such as H_2BDC, H_2BPDC, trident trimesic acid (H_3BTC) and 4,4',4''-benzene-1,3,5-triyl-tribenzoic (H_3BTB) with the order of increasing length. It was found that the porous carbon prepared with H_3BDC displayed the highest de-
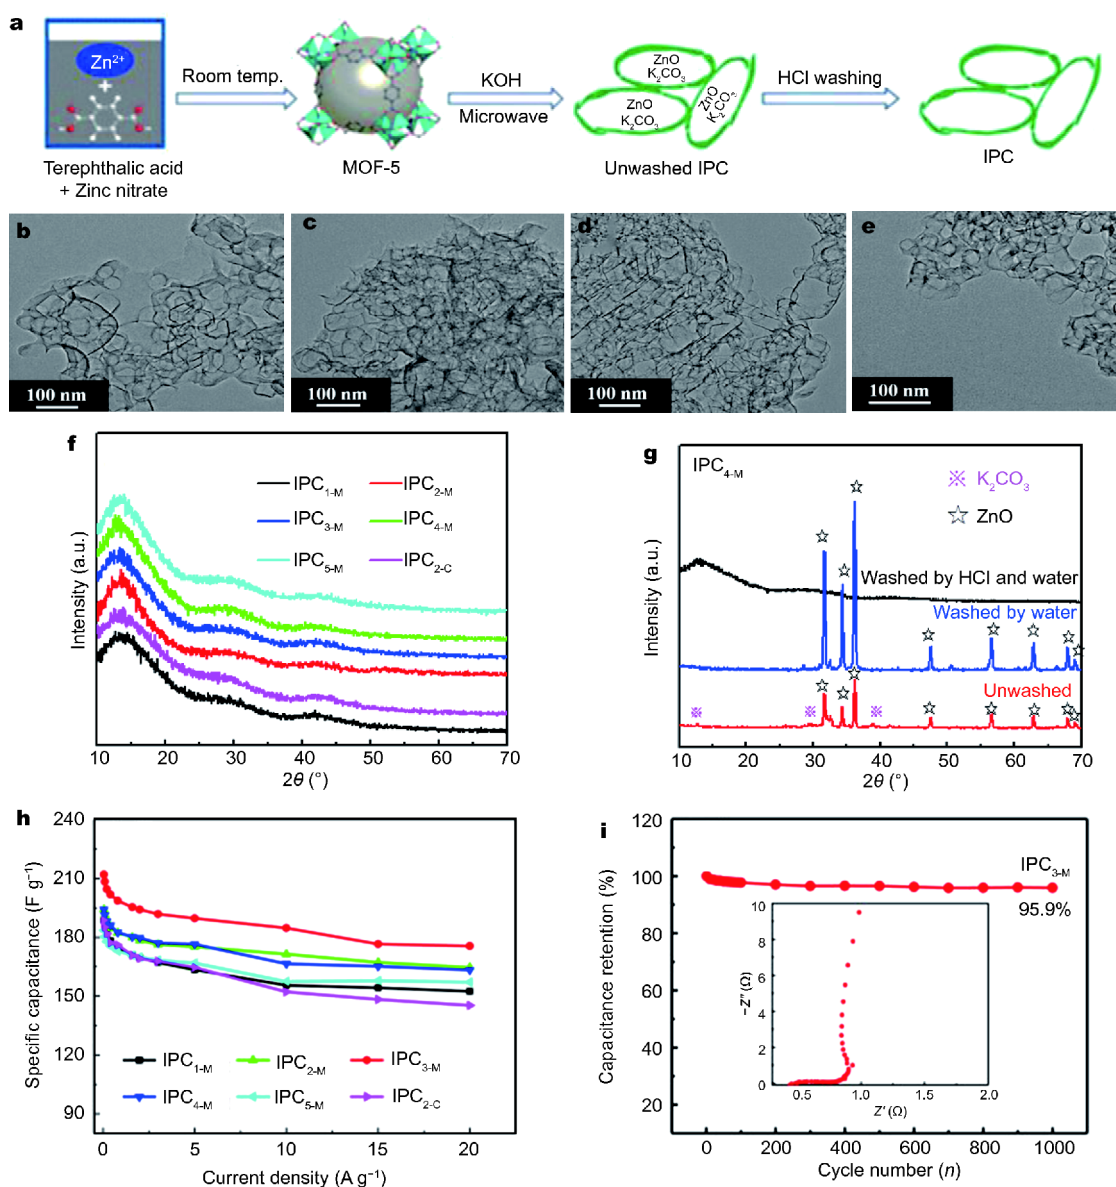

Figure 10 (a) Fabrication schematic of 3D IPCs. TEM images of IPC$_{2-M}$ (b), IPC$_{3-M}$ (c), IPC$_{4-M}$ (d) and IPC$_{5-M}$ (e). gree of graphitization. In contrast to the results of Lee *et al.* [48], the porous carbon materials showed higher SSA as the length of the organic ligand chain, or "strut" length, decreased. Hence, the highest SSA of 2,816 m^2 g^{-1} was measured for the porous carbon material using H$_2$BDC. A specific capacitance of 170 F g^{-1} was calculated for this material in 6 mol L^{-1} KOH at a scan rate of 1 mV s^{-1}, together with 98% capacitance retention after 5,000 cycles, indicating the stable and ordered structural porous carbon. The result shows that a large surface area, high

porosity and high conductivity may enhance the capacitance of porous carbons.

Yu *et al.* [62] proposed a unique route to form 3D interconnected porous carbons (IPCs) derived from MOF-5 *via* microwave-assisted KOH activation (Fig. 10a–e). The MOF-5 was prepared by H$_2$BDC and zinc nitrate at room temperature. Then, KOH was used to activate the MOF-5. Finally, acid etching was used to obtain IPCs. Fig. 10f shows the XRD patterns of IPCs with different MOF-5 to KOH mass ratios. It was found
Figure 11 (a, b) Schematic of the fabrication of the Al-MOF, metal organic gels drying with supercritical CO_2 (MOA) and after further carbonization (denoted as MOA-C), metal organic drying with air (MOX) and after further carbonization (denoted as MOX-C); (c, d) photographs of as-prepared MOX and final carbon products (MOX-C); (e) photographs of as-prepared MOA and MOA-C. that the SSA of IPC_{4-M} (MOF/KOH ratio was 4:1) was the highest with 1,595 $m^2\,g^{-1}$, and the associated pore distribution showed peaks around 0.4–0.9, 1.1–1.8 and 2–5 nm. However, despite not having the greatest SSA, the specific capacitance of IPC_{3-M} achieved the highest capacitance value of 212 $F\,g^{-1}$ at 0.05 $A\,g^{-1}$ in 6 $mol\,L^{-1}$ KOH electrolyte (Fig. 10h). The capacitance retention rate for the material was 95.9% (Fig. 10i) after 1000 cycles. The relatively high electrochemical performance IPC_{3-M} displayed was attributed to the bigger average pore size (3.39 nm), larger surface area (1,515 $cm^2\,g^{-1}$) and lower internal resistance, charge-discharge resistance (Fig. 10i), which facilitated the ion diffusion as well as promoted the

contact between electrolyte and electrode.

Xia *et al.* [63] obtained a whole piece of carbon aerogel material from a metal organic wet gel (Al-MOF), which was prepared using aluminum nitrate and H_3BTC *via* a solvothermal approach. The Al-MOF was then dried in supercritical CO_2, resulting in MOA. After further carbonization and hydrochloric acid etching to remove the Al, a carbonaceous metal organic aerogel was formed which was denoted as MOA-C. For comparison in this study, MOX was formed by directly drying the Al-MOF in an oven at 80°C. The material obtained after carbonization and activation, was labelled as MOX-C (Fig. 11a–e). Meanwhile, Mahmood *et al.* [64] prepared carbon
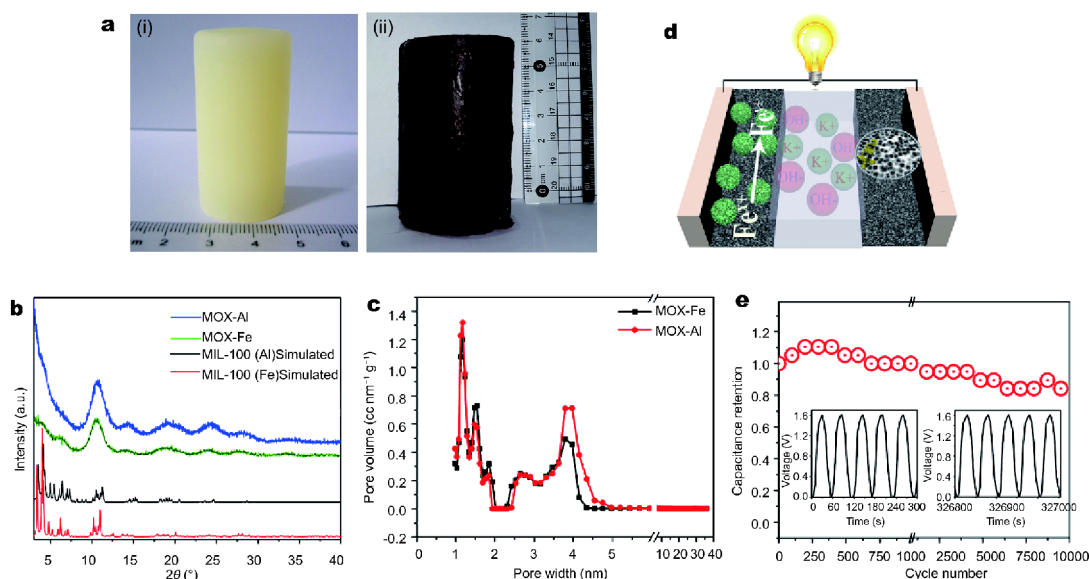

Figure 12 (a) Photographs of MOX-Al (i) and MOX-Fe (ii); (b) XRD patterns of MOX-Al and MOX-Fe; (c) pore size distribution of MOXs; (d) the schematic diagram of ASC; (e) the cyclic stability of ASC. Reproduced with permission from Ref. [64], Copyright 2016, American Chemical Society.

gel using a similar method, schematically represented in Fig. 11f. The electrochemical properties of MOXC-Fe and nanoporous carbon were investigated not only in a three electrode cell but also an ASC constructed from these two materials. MOXC-Fe exhibited specific capacitance of 600 F g^{-1} in 6 mol L^{-1} KOH electrolyte, at a current density of 1 A g^{-1}. The high performance is attributed to the improved pseudocapacitance derived from Fe/Fe-oxide transitions, in combination with EDLC provided by the carbon material framework. The stability of MOXC-Fe carbonized at 700°C was enhanced due to a near ideal thickness of carbon material decorating the Fe_3O_4/Fe metallic centers of the framework. Furthermore, the nanoporous carbon exhibited a specific capacitance of 207 F g^{-1} in 1 mol L^{-1} KOH electrolyte at a scanning rate of 250 mV s^{-1}. The EDLC was improved due to the higher surface area and hierarchical pore size distribution. The high SSA of 1,757 m^2 g^{-1} for nanoporous carbon was ascribed to NaOH activation. The electrochemical performance of nanoporous carbon in this article outperformed most of the carbon materials delivered from MOFs that have been previously reported [5,65]. The ASC not only displayed a relatively high specific capacitance of 202.5 F g^{-1} in 6 mol L^{-1} KOH electrolyte at 0.5 A g^{-1}, but also good cyclic stability with greater than 80% capacitance retention after 10,000 cycles (Fig. 12e). The excellent electrochemical performance of supercapacitors was ascribed to the higher capacitance performance of positive and negative electrode material. When combined

together into an ASC device, the independent stability of each electrode will influence the overall stability of the supercapacitor device.

MOFs in combination with other materials as carbon sources

Although the organic ligands can serve as carbon precursor of MOFs, other carbon sources are also used to prepare porous carbon materials, resulting in unique porous and stable carbon materials.

Liu *et al.* [66] added furan methanol (FA) as a carbon source to the reaction solution of MOF-5 and investigated the electrochemical properties of the prepared carbon materials, at different temperatures. Jin *et al.* [67] applied glucose as a carbon source with MOF-5 and then investigated its electrochemical performance with ionic liquid electrolyte. Lei *et al.* [68] combined the approach of mesoporous molecular sieves with ZIF-67. In this work a ZIF-67 coating with SiO_2/RF, which formed using tetraethylorthosilicate (TEOS), resorcinol and formaldehyde, was prepared through one-step method (denoted as ZSR). For comparison, ZIF-67/SiO_2/RF-M was prepared by two steps in which ZIF-67 was firstly formed and by further carbonization and removal of silica, an N-doped carbon was obtained, which is denoted as carbon-ZSR. The material possesses an ordered mesoporous structure and large SSA, as can be seen in Fig. 13. The SSA of the carbon-ZSR was measured to be 683 m^2 g^{-1} and the associated pore volume was 0.897 cm^3 g^{-1}. The pore size

distribution showed a strong peak at 3.96 nm. Electrochemical performance testing resulted in a specific capacitance of 305 F g^{-1} in 1 mol L^{-1} H$_2$SO$_4$ electrolyte at 1 A g^{-1}, together with a retention rate of 98.4% after 5,000 cycles at 10 A g^{-1}.

Metal compounds (metal oxides or metal sulphides)
Transition metal oxides are promising candidate for supercapacitor electrodes due to the multiple oxidation states/structures that enable rich redox reactions and high specific capacitance [69–71]. Thus, enormous effort has been made to design a robust and stable structure which lead to the superior energy density and long lifetime of metal compounds [72,73]. The metal compound prepared by annealing MOFs shows a relatively high cyclic stability than the other methods due to the pore shape and unique structure [74,75].

Meng *et al.* [76] obtained Co$_3$O$_4$ from Co-MOF *via* a

solvothermal method, followed by low temperature annealing. The unique Co-MOF crystal was formed by cobalt nitrate, azobenzene-3,5,4'-tricarboxylic acid (H$_3$ATBC), and 4,4'-bipyridine (BPY) (Fig. 14a). The carboxylate groups of H$_3$ATBC ligand were combined with Co(II) ions, resulting in the formation of a 2D layered structure (Fig. 14b). Furthermore, BPY ligand was used to combine the two layers with linear N, N-donor spacers to form an overall bi-layer gallery. In addition, the 2D bi-layer nets are then further stabilized by both π-π stacking and hydrogen bonding interactions. Thus, the overall 3D polycatenation (Fig. 14c) array superstructure was formed. The SSA of Co$_3$O$_4$ was 47.12 m^2 g^{-1} and pore diameter was measured to be 10.8 nm. The specific capacitance reached 150 F g^{-1} in 2 mol L^{-1} KOH electrolyte at 1 A g^{-1}. Remarkably, there was no significant capacitance loss observed over 3,400 cycles at 1 A g^{-1} (Fig. 14d, e), thereby demonstrating excellent cyclic stability, which
Figure 15 SEM images of Ce-MOF (a) and CeO₂ (b). (c) Specific capacitance of CeO₂ in different electrolytes. (d) Cyclic stability of CeO₂ in different electrolytes and coulombic efficiency. Reproduced with permission from Ref. [77], Copyright 2014, the Royal Society of Chemistry.

in turn suggests strong chemical structural stability. The diffusion kinetics within the electrode was enhanced by the porous spaces created by Co_3O_4 aggregates, which served as reservoirs for electrolyte ions. The amorphous porous structure of the Co_3O_4 materials also provides abundant electroactive surface sites for redox pseudocapacitance.

Maiti *et al.* [77] prepared brick-like CeO_2 (Fig. 15a, b) by thermal treatment of Ce-MOF used as a sacrificial material at 650°C. The well-defined, aligned nanobars of Ce-MOF (length: 0.5–1.0 μm, width: 50–100 nm) were formed *via* solvothermal method with metal cerium salt and H_3BTC [78]. The SSA of CeO_2 was calculated to be 77 m² g⁻¹, while that for Ce-MOFs is 27.3 m² g⁻¹. The superior surface area of CeO_2 is presumably owed to the unique brick-upon-tile morphology, which contained a large amount of voids. In 3 mol L⁻¹ KOH electrolyte, the specific capacitance of CeO_2 was 502 F g⁻¹ at 0.2 A g⁻¹ (Fig. 15c). The addition of 1 mol L⁻¹ $K_4Fe(CN)_6$ into the 3 mol L⁻¹ KOH electrolyte resulted in a remarkably high capacitance of 1,204 F g⁻¹ at 0.2 A g⁻¹. To describe the mechanism for this increase, the $Fe(CN)_6^{4-}/Fe(CN)_6^{3-}$ redox-active couple in the electrolyte acts as an electron buffer source and further supplements the Ce^{IV}/Ce^{III} redox reactions at the electrode/electrolyte interface. Furthermore, with the mixed electrolyte the capacitance showed no decrease after 5,000 cycles (Fig. 15d). The high rate capability and cyclic stability indicate that the addition of new redox couples can facilitate the ionic diffusion, thereby promoting the redox kinetics. In this work, the pseudocapacitance was improved due to the increased availability of electrons from the redox reaction.

Chen *et al.* [79] synthesized NiCo oxides by the annealing method, in the process of which Co and Ni act as the central metal ions (Fig. 16a). Different kinds of NiCo oxides were formed with different Ni/Co ratios. A specific

capacitance of 797 F g⁻¹ (Fig. 16b) was achieved for $NiCo_2O_4$ (Ni/Co=1:2) in 6 mol L⁻¹ KOH at 1 A g⁻¹, which was ascribed to the abundant redox active sites of $NiCo_2O_4$. In addition, the specific capacitance remained over 500 F g⁻¹ after 10,000 cycles, demonstrating a reasonably long cycle life (Fig. 16c).

Salunkhe *et al.* [80] prepared nanoporous carbon and nanoporous Co_3O_4 by annealing ZIF-67. The nanoporous carbon material was prepared by high temperature carbonization, while the nonporous Co_3O_4 by low temperature annealing in air (Fig. 17a). The nanoporous carbon and Co_3O_4 were used to assemble an ASC (Fig. 17c). The SSAs of nanoporous carbon and Co_3O_4 were approximately 350 m² g⁻¹ and 148 m² g⁻¹, respectively. In a three-electrode configuration, the specific capacitance of Co_3O_4 reached 504 F g⁻¹ in 6 mol L⁻¹ KOH electrolyte at 5 mV s⁻¹ (Fig. 17b). The ASC displayed a specific capacitance of 101 F g⁻¹ at 2 A g⁻¹ in 6 mol L⁻¹ KOH electrolyte, together with 89% capacitance retention after 2,000 cycles.

Liu *et al.* [81] obtained $Co_9S_8@C$ *via* carbonization of Co-MOF. Cobalt chloride, thiophene-2,5-dicarboxylate (TDC) and BPY were used to prepare Co-MOF. Following this, S-doped and N-doped carbon cuboid ($Co_9S_8@SNCC$) and carbon bulk ($Co_9S_8@SNCB$) porous materials were formed by further hydrochloric acid etching (Fig. 18). $Co_9S_8@SNCB$ and $Co_9S_8@SNCC$ were prepared by hydrothermal method and solvothermal method, respectively. The SSA of $Co_9S_8@SNCC$ and $Co_9S_8@SNCB$ were measured to be 212.1 and 88.1 m² g⁻¹, respectively. The specific capacitance of $Co_9S_8@SNCC$ was 429 F g⁻¹ which was higher than that of $Co_9S_8@SNCB$ (320 F g⁻¹). Both results were obtained in 6 mol L⁻¹ KOH electrolyte, at a current density of 1 A g⁻¹. The relatively high capacitance of $Co_9S_8@SNCC$ is attributed to its higher SSA and unique porous structure which provides

sufficient space for electrolyte transport during charge/discharge process. Furthermore, the intimate interaction between the graphitic carbon and Co_9S_8 nanoparticles enables sufficient electron transport to the redox active sites [82–85]. After 5,000 cycles, the capacitance retention of Co_9S_8@SNCC was 98%, demonstrating excellent cyclic stability.

MOFs AND THEIR DERIVATIVES AS COMPOSITE SUPERCAPACITOR ELECTRODES

Although MOFs display a large SSA and abundant active sites, the structure stability and electrical conductivity are not satisfactory. Adding surfactants and ion doping are effective strategies to construct a robust and stable structure of electrode materials. Furthermore, the low electrical conductivity increases irreversible capacitance and slows down the ion diffusion. Hence, conductive fillers like carbon materials and conductive polymers have been investigated to address these issues [24,25,86]. The composites can be prepared through a one-step method where the other materials participate in the reaction of preparing MOFs. On the other hand, the combination of MOFs and other materials can achieve after preparing the MOFs.

The composites of MOFs and additional materials used as supercapacitor electrodes

Surfactant as additional material
Surfactants play a key role in the synthesis of porous materials because they can act as sacrificial templates

[87,88]. In the process of synthesizing MOFs, surfactants can be used as a sacrificial template to obtain micropores and mesopores structure. Surfactants can be adsorbed onto the MOF structure acting as a structural guide agent during the synthesis of MOFs, creating an ordered pore structure [89]. There are three kinds of surfactants that are commonly used: polymer surfactants (triblock copolymer Pluronic F127, triblock copolymer P123, etc.), nonionic (polyols, amines), and ionic (alkyl quaternary ammonum salts) surfactants.

Meng *et al.* [90] synthesized spindle-like Fe-MIL-88B-NH_2 using the polymer surfactant F127 as a structure-directing agent and template. The Fe_3O_4/carbon composite was prepared by a well-controlled, incomplete annealing process (Fig. 19). The SSA of 37.7 m² g⁻¹ was achieved for the Fe_3O_4/carbon composite. At 1 A g⁻¹, the specific capacitances of this Fe_3O_4/carbon were calculated to be 86, 128, 138, 162 F g⁻¹ in 1 mol L⁻¹ KOH electrolyte at 0, 20°C, 40°C, 60°C, respectively. During the first 1000 cycles at 20°C, the specific capacitance of the electrode decreased slowly to 88% of the initial value, implying a somewhat stable electrode structure at 20°C. However, it was observed that the capacitance increased rapidly when the temperature was raised to 40°C, due to the decrease of internal resistance of electrolyte (Fig. 19e). After 1000 cycles at 40°C, an ice-bath was used to reduce the temperature to 0°C and another 1000 charge/discharge cycles were performed. The temperature was then returned to 20°C. After further 1000 cycles (4000 in total), the capacitance value of the electrode decreased to 83.3% of its initial capacity (Fig. 19f). The investigation of electrochemical performance at different temperatures lends

important insight into the suitability of an electrode material for practical applications. Therefore, it is of great significance to demonstrate that the prepared electrode materials were able to operate over a wide temperature range.

Salunkhe *et al.* [91] prepared nanoporous carbon materials by adding polyvinylpyrrolidone (PVP) to large particle ZIF-8 and then subjecting the mixture to further carbonization treatment. In this process, PVP acted as a structure-directing agent and participated in the formation of a ZIF-8 backbone. Cao *et al.* [92] also added PVP during the synthesis of porphyrin paddlewheel framework-3 (PPF-3) (Fig. 20). The PVP selectively attaches onto the surface of MOFs, controlling the vertical growth of PPF-3 MOF crystals and thereby resulting in the formation of 2D PPF-3 nanosheets. 2D CoSNC nanocomposites are then formed by a simultaneous sulfidation and carbonization process of the obtained 2D PPF-3 nanosheets (Fig. 20e). In the obtained CoSNC nanocomposites, the $CoS_{1.097}$ nanoparticles were dispersed uniformly in the nitrogen-doped carbon matrix during the thermal treatment. This surfactant-assisted synthetic method is an efficient approach to construct 2D functional hybrid materials from MOF nanosheets with the specific capacitance found to be 360.1 F g^{-1} in 2 mol L^{-1} KOH electrolyte at 1.5 A g^{-1}.

Metal materials as additional materials
Li *et al.* [93] reported novel hierarchical double-shelled NiO/ZnO hollow spheres produced by a one-step solvothermal method, without any template, surfactant, or calcination (Fig. 21a). The Ni-Zn MOF was prepared with H_2BDC, zinc nitrate and nickel nitrate. The XRD pattern of Ni-Zn MOF matches well with the Zn-doped Ni-based MOF material [94], in which a double-layered structure with an enlarged interlayer distance was formed due to a chain like $M(OH)_3$ secondary building unit of Zn-doped Ni-MOF. The specific capacitance of NiO/ZnO electrode was calculated to be 497 F g^{-1} in 3 mol L^{-1} KOH electrolyte at 1.3 A g^{-1}. Remarkably, the specific capacitance increased by 17.1% of its initial capacity after 2,000 cycles. The electrochemical performance benefited from the double shelled structure and high porosity, which facilitates the transfer of ions and electrons at the electrode/electrolyte interface, and can also alleviate the volume change during the charge/discharge process.

Yang *et al.* [94] also fabricated layered structural Zn-doped Ni-MOF by adding Zn ions into the reaction system of the MOF (Fig. 21b). The Zn-doped Ni-MOF structure becomes bigger as the doping amount of Zn increases, as the larger Zn^{2+} ions partially, or wholly replace the smaller Ni^{2+} ions. At 0.25 A g^{-1}, the specific capacitance of MOF-2 (Zn-doped Ni-MOF with $ZnCl_2$,

0.0456g) reached 1,620 F g^{-1} in 6 mol L^{-1} KOH electrolyte. In addition, the specific capacity retention ratio was 91% after 3,000 cycles. The results showed that MOF-2 not only displayed excellent capacitive performance, but also a strong cyclic stability. These were attributed to the intrinsic characteristics and morphology. The layered structure of Zn-doped Ni-MOF with its enlarged inter-

layer distance (Fig. 21b) ensured more efficient ion intercalation and deintercalation, thereby improving the pseudocapacitance.

Weng et al. [95] prepared a MoS$_2$/microporous carbon (MPC) composite by loading ZIF-8 on MoS$_2$ nanosheets and subjecting this to further carbonization. The capacitance retention was 98% of the initial capacity after 3,000 cycles, while specific capacitance of 189 F g^{-1} was achieved in 1 mol L^{-1} H$_2$SO$_4$ electrolyte at 1 A g^{-1}. MoS$_2$ wrapped with MPC promotes the cyclic stability, and gave rise to a new approach to building high performance supercapacitor electrodes.

Carbon-based materials as additional materials
Graphene and carbon nanotubes are widely investigated conductive fillers to the supercapacitor electrodes due to their superior electrical conductivity and large SSA [96,97]. Moreover, the two dimensional (2D) structure of graphene and one dimensional (1D) structure of carbon nanotubes can serve as the substrate due to the excellent mechanical and chemical stability.

Li et al. [98] prepared multi-wall carbon nanotubes (MWCNTs)/porous carbon material by carbonizing (800°C) and acid treating the MWCNTs composites, which decorated the ZIF-8 onto the surface (Fig. 22). The MWCNTS was functionalized by KMnO$_4$ and HNO$_3$. The specific capacitance value of MWCNTs/nanoporous carbon-Large was measured to be 302.2 F g^{-1} in 1 mol L^{-1} H$_2$SO$_4$ electrolyte, at a current density of 2 A g^{-1}. Furthermore, the loss of capacitance as measured by cyclic voltammetry, was only 4.2% after 10,000 cycles at a scan rate of 100 mV s^{-1}. This strong cyclability indicates the MWCNTs/nanoporous carbon-Large may be a promising material for supercapacitor electrodes.

Xu et al. [99] also obtained hybrid carbon nanotubes (CNTs)/nitrogen-doped carbon polyhedra by carbonizing (1000°C) CNTs/ZIF-8, which come from *in situ* growth of ZIF-8 on the CNTs substrate. When the scanning rate was 5 mV s^{-1}, the specific capacitance reached 308.0 F g^{-1} in 1 mol L^{-1} H$_2$SO$_4$ electrolyte. Wen et al. [100] prepared Ni-MOF/CNTs by loading Ni-MOF on CNTs. Nickel chloride and H$_2$BDC were used to prepare Ni-MOF. The specific capacitance of the as-prepared Ni-MOF/CNTs was 1,765 F g^{-1} in 6 mol L^{-1} KOH electrolyte, which was greater than that of pristine Ni-MOF (1,080 F g^{-1}) at 0.5 A g^{-1}. The nanoporous structure of Ni-MOF can improve the penetration of the electrolyte, thereby increasing its contact area with electrochemically active sites. Meanwhile, the CNTs wrapped with Ni-MOF can improve the transport of electrons from the active compo-
Figure 22 (a) Schematic for the fabrication process of MWCNTs/nanoporous carbon-Small/Middle/Large. (b, c, d) TEM images of MWCNTs/nanoporous carbon with different sizes. nent to the current collector during the charge/discharge process.

Zhang et al. [101] prepared CNTs/Mn-MOF by growing Mn-MOF on CNTs. The manganese acetate and ammonium phthalate $(NH_4)_2C_8H_4O_4$ were used to prepare Mn-MOF. The carboxylic groups on CNTs acted as nucleation centers for subsequent Mn-MOF loading. The specific capacitance was calculated to be 202.8 F g^{-1} in 1 mol L^{-1} Na$_2$SO$_4$ electrolyte at 1 A g^{-1}.

Zhang et al. [102] obtained ZnO QDs/carbon/CNT (650°C) and PNC/CNTs (1000°C) by thermal treatment of ZIF-8/CNTs. ZnO QDs/carbon/CNTs delivered a specific capacitance of 185 F g^{-1} at 0.5 A g^{-1} while PNC/carbon/CNTs displayed a specific capacitance of 250 F g^{-1} at 1 A g^{-1} in 1 mol L^{-1} Na$_2$SO$_4$ electrolyte.

ZIF-8@reduced graphene oxides (RGO) was fabricated by Kim et al. [103] after annealing treatment of the ZIF-8/graphene composites. They found that the higher annealing temperature, the larger SSA, and the higher the pore volume obtained. Zhou et al. [104] prepared Ni-MOF@GO through the reaction of GO together with nickel nitrate and PTA (Fig. 23a). Different temperatures and different weight ratios of GO and MOF were used to prepare Ni-MOF and Ni-MOF@GO. It was found that when the reaction temperature was 180°C, in a three electrode configuration, the specific capacitance of Ni-MOF-HCl-180 with a modulator of HCl reached 1,457.7 F g^{-1} in 2 mol L^{-1} KOH electrolyte at 1 A g^{-1}. Moreover, the capacitance retention ratio was 83.4% of the initial capacity after 3,000 cycles (Fig. 23c). A maximum specific capacitance of 2,192.4 F g^{-1} was measured

with Ni-MOF@GO-3 of 3 wt.% GO weight ratio in 2 mol L^{-1} KOH electrolyte at 1 A g^{-1}, together with a capacitance retention ratio of 85.1% after 3,000 cycles. The as-prepared Ni-MOF@GO exhibited excellent electrochemical performance (Fig. 23b, c), showing tremendous potential as a supercapacitor electrode material.

Yin et al. [105] synthesized RGO@Co$_3$O$_4$ and Co$_3$O$_4$-RGO-Co$_3$O$_4$ by annealing GO@ZIF-67 and ZIF-67@GO@ZIF-67, which was prepared using GO, cobalt nitrate, 2-methylimidazole (MeIm) and PVP (Fig. 24). In their work, a SSA of 198.4 m^2 g^{-1} was achieved for RGO@Co$_3$O$_4$, which was about 5 times greater than that of Co$_3$O$_4$ (32.54 m^2 g^{-1}). The specific capacitance of RGO@Co$_3$O$_4$ was calculated to be 546 F g^{-1} in 6 mol L^{-1} KOH electrolyte at 0.5 A g^{-1}. The porous structure of this composite material can not only improve the permeability of the electrolyte, shortening the diffusion distance for ions, but also reduces the volume change of the electrode during the charge/discharge process. Furthermore, the higher surface area, as compared with the Co$_3$O$_4$-only films, offers increased contact area between electrolyte and electrode. In addition, the electrochemical performance of the composites films was enhanced due to the higher conductivity of the incorporated RGO.

Additional materials after MOFs are prepared

Organic compounds as additional materials
Wang et al. [106] reported a novel composite polyaniline-ZIF-67-carbon cloth (PANI-ZIF-67-CC) (Fig. 25). Beginning with carbon cloth, ZIF-67 was coated onto the
Figure 23 (a) Illustration of Ni-MOFs with graphene oxide (GO) nanosheets; (b) the specific capacitance of Ni-MOF@GO with different GO weight ratio; (c) cyclic stability of Ni-MOF-HCl-180 and Ni-MOF@GO-3. Reproduced with permission from Ref. [104], Copyright 2016, American Chemical Society.

Figure 24 (a) Schematic illustration of the synthesis processes of RGO@Co_3O_4 and Co_3O_4-RGO-Co_3O_4. SEM images of GO@ZIF (b); RGO@Co_3O_4 (c); ZIF/GO/ZIF (d) and Co_3O_4-RGO-Co_3O_4 (e). Reproduced with permission from Ref. [105], Copyright 2016, Elsevier.

cloth, and then following this, PANI was deposited by an electrochemical process [107]. In this study, carbon cloth serves as the substrate on which the active material is formed, and is able to be retained as the current collector for device construction. The advantages of this procedure are the cloth simplifies the production route, and further offers low cost and good flexibility. The chains of PANI can link up the isolated MOF and act as bridges for electrons transportation between the external circuit and

the internal surface of MOFs (Fig. 25g). PANI-ZIF-67-CC exhibited a SSA of 73 m^2 g^{-1} which was lower than that of ZIF-67. The areal capacitance of PANI-ZIF-67-CC was measured to be 2,146 mF cm^{-2} in 3 mol L^{-1} KCl electrolyte at 10 mV s^{-1}. Moreover, the electrical conductivity of the PANI-ZIF-67-CC was increased due to the deposition of PANI (Fig. 25g), resulting in enhanced rate performance.

Guo *et al.* [108] prepared carbonized Zn-MOF/PANI

Figure 25 Schematic of the two-step fabrication of PANI-ZIF-67-CC and SEM images of (a, b) carbon cloths, ZIF-67-CC (c, d), and PANI-ZIF-67-CC (e, f). Figure 26 (a) CV curves of AQ-NPCs, pure NPCs and AQ at 10 mV s^{-1}. (b) CV curves of TN-NPCs, pure NPCs, NQ and TCBQ at 10 mV s^{-1}. (c) The CV curves of ASC at 10 mV s^{-1}. Reproduced with permission from Ref. [109], Copyright 2017, Elsevier.

(ZMP) *via in situ* chemical oxidative polymerization. Typically, carbonized Zn-MOF was obtained by using zinc nitrate, 8-hydroxyquinoline and subsequent annealing treatment. The addition of carbonized Zn-MOF enhanced the electrical conductivity of PANI and the stability of the structure. Furthermore, the layered structure of carbonized ZMP can reduce the transmission distance of electrons and diffusion resistance of electrolyte. Carbonized ZMP-0.04 with 0.04 g of MOF addition amount displayed a maximum specific capacitance of 477 F g^{-1} in 1 mol L^{-1} H$_2$SO$_4$ electrolyte at 1 A g^{-1}.

Guo *et al.* [109] developed a general strategy to fabricate nitrogen-doped porous carbon (NPCs) material for supercapacitor electrodes using ZIF-8 as a sacrificial template and modification of pure anthraquinone (AQ), mixed naphthoquinone (NQ) and tetrachlorobenzoquinone (TCBQ). The TCBQ&NQ-NPCs (TN-NPCs) exhibited higher electrochemical activity than TCBQ and NQ. AQ-NPCs and TN-NPCs have good stability due to the π-π stacking between electroactive organic compounds (AQ, TN) and NPCs. Furthermore, electroactive organic AQ, NQ and TCBQ in the H$_2$SO$_4$ electrolyte can participate in the redox reaction and then enhance the pseudocapacitance (Fig. 26). The SSA of as-prepared TN-NPCs was found to be 356 m^2 g^{-1}, which was higher than that of AQ-NPCs (268 m^2 g^{-1}). TN-NPCs showed a specific capacitance of 392 F g^{-1} in 1 mol L^{-1} H$_2$SO$_4$ electrolyte, which was higher than that of AQ-NPCs exhibiting 373 F g^{-1} at the current density of 1 A g^{-1}. On the other hand, the rate capabilities of AQ-NPCs and TN-NPCs at 50 A g^{-1} were 83.2% and 76.9% with aspect to that at 1 A g^{-1}, indicating that the pore diameter and higher conductivity had a positively impact on charge/discharge process. It was also found that the specific capacitance of AQ-NPCs was proportional to the scanning rate, which demonstrates that the AQ-NPCs are with a suitable pore structure. For the ASCs constructed in this study, AQ-NPCs were used as negative electrodes while TN-NPCs as positive electrodes. The specific capacitance value of AQ-NPCs//TN-NPCs supercapacitor was 86 F g^{-1} in 1 mol L^{-1} H$_2$SO$_4$ electrolyte at 1 A g^{-1}, together with 75.3% capacitance retention ratio after 5,000 cycles at 5 A g^{-1}. The electrochemical performance of the supercapacitor benefited from the porous structure of the positive and negative electrodes, which can ensure enough electrolyte ions for EDLC and organic redox reactions. Furthermore, the redox reactions of the electroactive organic molecules in the electrode were not
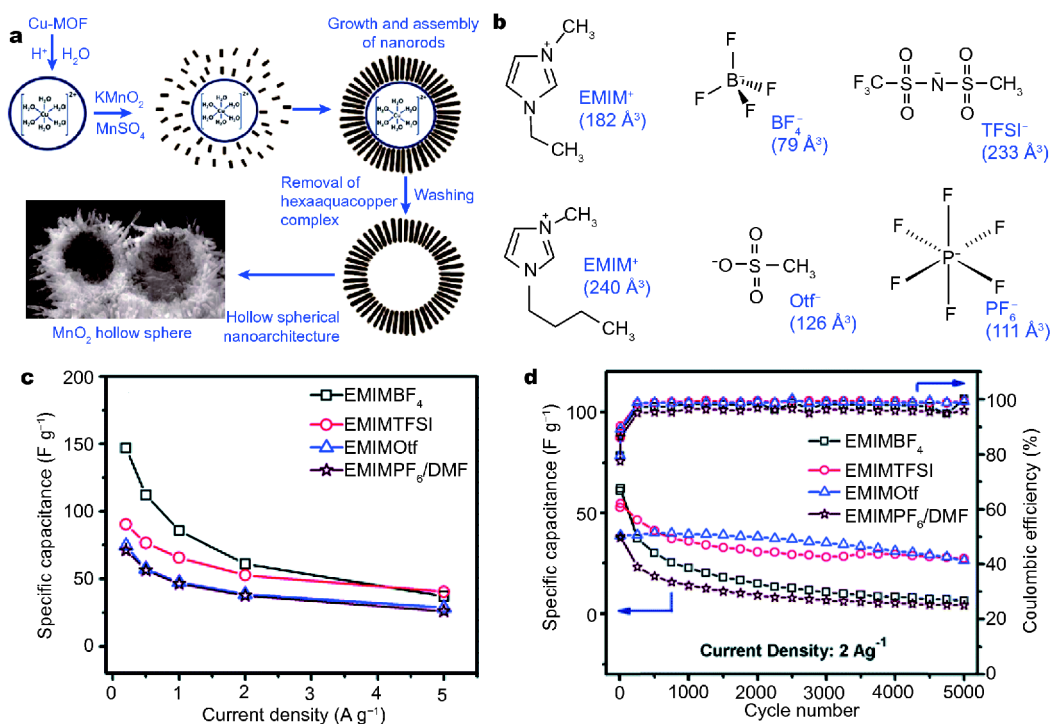

Figure 27 (a) The formation mechanism of MnO_2 hollow spheres; (b) chemical structure representation of the constituent ions in the ionic liquid electrolytes; (c) the specific capacitance of AC//IL//MnO_2 ASC in different electrolytes; (d) cyclic stability of AC//IL//MnO_2 ASC in different electrolytes. controlled by the diffusion, resulting in a kinetic condition for the self-matching of positive and negative electrode half reactions.

Metals as additional materials
Maiti *et al.* [110] fabricated hollow spherical nanostructured MnO_2 *via* low temperature solvothermal method under acidic conditions (Fig. 27a). The hollow spherical nanostructured MnO_2 was formed by the unstable metal ligand bonding in Cu-BTC. The Cu^{2+} and the water molecules are coordinated to act as nucleation sites in the acidic conditions, which is a key part. The SSA of MnO_2 was measured to be 85 $m^2 g^{-1}$, with a 16 nm diameter pore mode. It is proposed that the smaller electrolyte anions achieves contact on a greater surface area of the electrode material, resulting in a higher EDLC (Fig. 27b). Therefore, the superior electrochemical performance with a specific capacitance of 147 $F g^{-1}$ at 0.2 $A g^{-1}$ was measured in the 1-ethyl-3-methylimidazolium tetrafluoroborate (EMIMBF) electrolyte (Fig. 27c, d).

Jiang *et al.* [111] firstly synthesized the layered double hydroxides (LDHs) non-spherical structures by ZIF-67 nanocrystals as templates. The Ni-Co nanocages well inherited the rhombic dodecahedral shape of the ZIF-67

templates, and the shell was composed of nanosheets assembled with an edge-to-face stacking. Specifically, a hollow structure was obtained after precipitation of the corresponding shell materials and acidic etching of the sacrificial template. In order to form nanocages structure, the reaction kinetics needs to keep balance between the precipitation of the shell and the simultaneous template etching. The Ni-Co LDH nanocages delivered a superior specific capacitance of 1,203 $F g^{-1}$ at 1 $A g^{-1}$ in 1 mol L^{-1} KOH electrolyte than Ni-Co LDH nanoparticles, together with excellent cycling stability (i.e., 90.2% of the initial capacity retained after 1000 cycles). However, the poor conductivity affects the overall performance of pseudocapacitance by reducing the energy efficiency.

Carbon-based materials as additional materials
Srimuk *et al.* [112] prepared a flexible electrode material using carbon fiber paper, which was spin-coated with the Hong Kong University of Science and Technology-1 (HKUST-1) Cu-MOF and RGO. The SSA of 10 wt.% RGO/HKUST-1 was 1,241 $m^2 g^{-1}$ and the average pore diameter was 8.2 nm. The specific capacitance of the constructed flexible electrode was measured to be 385 $F g^{-1}$ at the current density of 1 $A g^{-1}$ in 0.5 mol L^{-1}
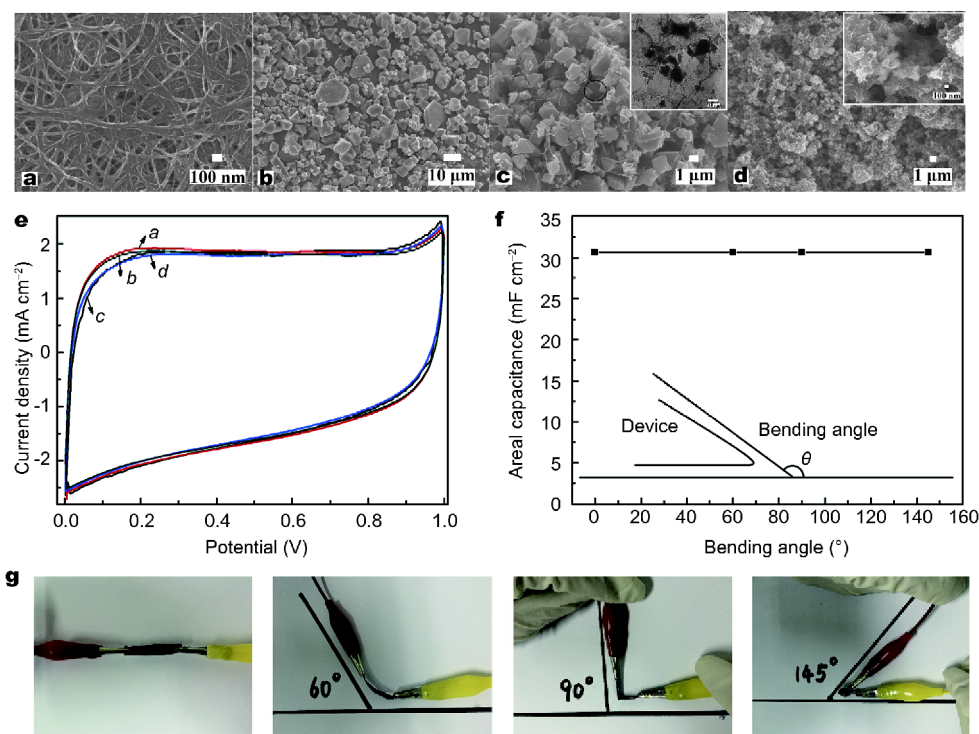

Figure 28 SEM images of carbon nanotube film (CNTF) (a) and HKUST-1 (b); (c) SEM image of H-1-15G, and the inset is a high resolution image; (d) SEM image of PEDOT/H-15G-CNTF, and the inset is a high resolution image; (e) the CV curves at 50 mV s^{-1} for solid-state supercapacitors bent at different angles; (f) the specific capacitance of the device bent at different angels and (g) the accompanying photographs. Na$_2$SO$_4$ electrolyte.

Fu *et al.* [113] synthesized a novel electrode material using poly(3,4-ethylenedioxythiophene (PEDOT). Firstly, HKUST-1 was prepared by solvothermal method. Then, a GO solution was added to the well-dissolved HKUST-1 precursors forming H-G hybrid materials. H-G hybrid materials were then loaded on carbon nanotube film (CNTF) to obtain H-G-CNTF. Finally, PEDOT/H-G-CNTF was prepared by electrochemical deposition of the PEDOT onto the H-G-CNTF (Fig. 28). A maximum SSA of 950 m^2 g^{-1} was achieved for H-15G, with an accompanying 5.5 nm average pore diameter. The PEDOT/H-15G-CNTF electrode showed an areal capacitance of 128 mF cm^{-1} in 3 mol L^{-1} KCl electrolyte at 10 mV s^{-1}. In addition, an all solid-state supercapacitor was assembled to further study the electrochemical properties employing PVA/H$_3$PO$_4$ as the gel electrolyte. A specific capacitance of 37.8 mF cm^{-2} was measured for the supercapacitor device at a scan rate of 5 mV s^{-1} (Fig. 28e). It is worth noting that the capacitance did not decrease under various bending conditions the supercapacitor device was subjected to (Fig. 28f, g).

Banerjee *et al.* [114] synthesized MOF-5$_{NiRGO}$ in bulk (gram scale) quantities. The composites were prepared by mixing Ni-doped MOF-5 with RGO (Fig. 29). The as-prepared MOF-5$_{Ni50\%\ RGO50\%}$ exhibited a specific capacitance of 758 F g^{-1} in 1 mol L^{-1} KOH electrolyte at 1 mV s^{-1}, which was much greater than that of MOF-5$_{Ni50\%}$ (380 F g^{-1}) and MOF-5 (90 F g^{-1}). Other than increasing the contact area between the electrode and electrolyte, the addition of RGO also enhanced the conductivity of the electrode, thereby promoting the efficiency of ion transport, resulting in higher capacitive performance.

CONCLUSION AND FUTURE PERSPECTIVES

In summary, MOF materials have attracted extensive attention in response to an ever increasing demand for high performance supercapacitor electrodes. In efforts to meet the criteria of the adjustable pore size distribution, high SSA, abundant active sites and excellent electrical conductivity of electrode, various nanoscale MOFs structures and their derivatives have been intensively explored. Currently, MOFs represent the strong candidate for supercapacitor electrodes due to their ordered porous
Figure 29 Schematic of the fabrication of MOF-5$_{NiRGO}$ applied as a supercapacitor electrode, and also depicted are the coexisting EDLC charge storage RGO, and the reversible redox reactions of Ni metal centers. structure combined with reversible intercalation of electrolyte ions. However, it is more effective to enhance capacitance by introducing pseudocapacitive materials into the MOF systems with porous structure. Although transition metal oxides are widely used as active materials to improve the capacitance due to their extremely high theoretical capacitance, the Faradaic reaction takes time to store charges at a level of full capacity of the electrode, and such pseudocapacitive electrodes suffer from low rate performance. Moreover, most active electrodes of transition metal oxides suffer from lower structural/chemical stability which greatly limits the cycle life of a supercapacitor. Coating carbon material onto MOFs and constructing double shell structure are common strategies to reduce the irreversible capacity loss caused in charge/discharge processes. The numerous examples of this demonstrate that rational architecture of MOFs materials, through combining carbon-based materials with polymer materials is an effective method to construct supercapacitor electrodes with the advantages of high capacity and long cycle life, making them promising for practical applications. Although most MOFs lack sufficient electrical conductivity, introducing materials with good electrical conductivity in MOFs system can endow fast

dynamic charge propagation, thereby enhancing the electrochemical performance. Thus, it is of great significance to investigate the nature of charge transport in these materials, and to design suitable conductive structural MOFs.

A wide potential window is often required to boost the energy of a supercapacitor. However, the obstacle in using aqueous electrolyte is the electrolysis of water when the voltage exceeds 1.23 V. The research of MOFs as supercapacitor electrodes is still concentrated at aqueous media and in the laboratory scale. Thus, more in-depth studies on solid-state supercapacitors with wider potential window are in need. Energy storage devices based on environmentally-friendly, low-cost and high-yield MOFs are anticipated to be commercially available in the future, based on the maturity of MOFs technology.

Author contributions   Zhao Y wrote the manuscript. Liu J organized the manuscript structure and contributed to the general discussion; Horn M and Motta N revised the manuscript. Hu M and Li Y con-tributed to the general contribution.

Conflict of interest   The authors declare that they have no conflict interest.

Yujie Zhao received her Master's degree from Chongqing University, China, in 2017. Currently, she is a PhD student at Beihang University, China. Her research interest is focused on functional nanomaterials and related energy applications.

Jinzhang Liu received his PhD degree in Condensed Matter Physics from Lanzhou University in 2006. He then continued his academic career in South Korea (2006–2011) and Australia (2011–2015). Currently, he is an associated professor at the School of Materials Science and Engineering of Beihang University. His research interests include the synthesis of carbon materials and their applications in supercapacitors and solar-powered desalination.
Yan Li is a professor of the School of Materials Science and Engineering of Beihang University. He received his PhD degree form Dalian University of Technology in 2001. His current research interests include shape memory materials, biomedical materials, supercapacitors and battery materials.

金属有机框架材料在超级电容器中的应用研究进展

赵昱颉[1], 刘金章[1*], Michael Horn[2], Nunzio Motta[2], 胡明俊[1], 李岩[1*]

摘要 金属有机骨架材料具有结构多样、孔径可调、比表面积大及化学反应活性位点丰富等优点，因此有望成为广泛应用于电化学储能器件的电极材料，如锂离子电池、燃料电池及超级电容器等. 近十年来金属有机骨架材料及其衍生物材料引起了广泛的研究与应用. 同时，金属有机骨架材料及其衍生的纳米材料作为电化学储能器件中的关键电极也受到了广泛的研究. 本文主要综述了近期金属有机骨架材料及其衍生物在超级电容器中的研究进展，讨论了金属有机骨架材料制备超级电容器电极材料的方法及其在电化学储能领域体现出的优异性能及特殊性质，同时也总结了近期金属有机骨架材料的衍生物如碳材料、金属材料及复合物在超级电容器中的研究进展，结果说明金属有机骨架材料在发展新一代超级电容器电极材料领域具有重要的作用. 最后讨论了金属有机骨架材料及其衍生物目前在超级电容器领域存在的问题以及未来可能的发展方向.
