Muscarinic M1–M5 acetylcholine receptors are G-protein-coupled receptors that regulate many vital functions of the central and peripheral nervous systems. In particular, the M1 and M4 receptor subtypes have emerged as attractive drug targets for treatments of neurological disorders, such as Alzheimer's disease and schizophrenia, but the high conservation of the acetylcholine-binding pocket has spurred current research into targeting allosteric sites on these receptors. Here we report the crystal structures of the M1 and M4 muscarinic receptors bound to the inverse agonist, tiotropium. Comparison of these structures with each other, as well as with the previously reported M2 and M3 receptor structures, reveals differences in the orthosteric and allosteric binding sites that contribute to a role in drug selectivity at this important receptor family. We also report identification of a cluster of residues that form a network linking the orthosteric and allosteric sites of the M4 receptor, which provides new insight into how allosteric modulation may be transmitted between the two spatially distinct domains.

The M1–M5 muscarinic acetylcholine receptors constitute an important family of class A G-protein-coupled receptor (GPCRs) activated by the neurotransmitter, acetylcholine¹. Both the M1 and M4 receptors have been associated with learning, memory, and cognition^{2,3} and have emerged as attractive targets for the treatment of various central nervous system disorders, including Alzheimer's disease, schizophrenia, and drug addiction^{4–6}. However, the orthosteric acetylcholine-binding site is highly conserved, and the clinical translation of compounds targeting these receptor subtypes has remained largely unsuccessful owing to adverse side effects from off-target activity at peripheral M2 and M3 receptor subtypes^{7–9}. Encouragingly, muscarinic receptors possess spatially distinct allosteric binding sites that offer greater potential for selective receptor targeting^{10–12}, and the M1 and M4 receptors are prime examples where highly selective positive allosteric modulators (PAMs) with central nervous system activity and preclinical efficacy have been identified^{4,13–17}.

So far, however, the structural basis of drug action at these receptor types has been largely restricted to mutational analyses^{18–21}, with the only reported muscarinic receptor crystal structures being of the M2 and M3 subtypes^{22,23}. Thus, to better understand the molecular basis for orthosteric and allosteric drug interactions with the M1 and M4 receptors, we sought to obtain high-resolution X-ray crystal structures of both subtypes. To gain additional insight into potential mechanisms of allosteric modulation, we complemented our findings with active-state homology modelling to rationalize the effects of targeted mutations on the interaction between a well-characterized PAM and acetylcholine at the M4 receptor.

Crystallization of the M1 and M4 receptors

To determine the structures of the M1 and M4 muscarinic receptors, we used protein engineering and lipidic cubic phase methodology^{24,25}. Both receptors were crystallized in the presence of the high-affinity and clinically used inverse agonist, tiotropium (Spiriva), to stabilize

the inactive state. Intracellular loop 3 (ICL3) of the M1 receptor was replaced with a T4 lysozyme fusion protein, and in the case of the M4 receptor a minimal T4 lysozyme (mT4L)²⁶ fusion was used to aid crystallization (Extended Data Fig. 1). It was also necessary to remove the first 21 residues of the amino (N) terminus from the M4 receptor to improve diffraction. The M1 receptor was also crystallized with the N2Q and N12Q mutations to remove glycosylation sites, and, unintentionally, an N110Q^{3,37} mutation. Importantly, the binding affinities of [³H]QNB (M1 receptor), [³H]NMS (M4 receptor), acetylcholine, or tiotropium were not significantly different at either fusion construct compared with the wild-type receptor, suggesting that the alterations did not perturb the orthosteric site; the M1 N110Q^{3,37} mutation also had no significant effect on receptor functionality in the absence of T4 lysozyme (Supplementary Table 1). The M1 and M4 structures were subsequently determined to a resolution of 2.7 Å and 2.6 Å, respectively (Extended Data Table 1).

Comparison of muscarinic receptor structures

Overall, the structures of the M1 and M4 receptors are similar to the previously solved inactive M2 and M3 receptors^{22,23}, with similar positioning of the seven-transmembrane (TM1–7) bundle and root mean squared deviations of 0.6–0.9 Å (Fig. 1a). Subtle differences between the receptors are observed on the extracellular and intracellular sides (Fig. 1b, c) corresponding to regions that are least conserved across the muscarinic subtypes (Extended Data Fig. 2). For example, the M2 receptor differs from the other receptors in the tilt and position of TM1 and TM7 (Fig. 1a, b). Notably, the M1 receptor was co-crystallized with a Flag peptide co-bound on the intracellular side, which makes extensive contacts with TM6 and ICL3 (Extended Data Fig. 3a, b), and probably contributes to observed differences in TM5, TM6, and a variable linkage between TM7–helix8 (Extended Data Fig. 3c). The M1-N110Q^{3,37} mutation has little effect on the M1 structure other than creating a slight bulge in TM4 due to the loss of a hydrogen bond with

Figure 1 | Structural comparison of the M1–M4 receptors. **a**, The overall view of the muscarinic structures is shown as cartoons aligned to the M3 receptor, with the M1 coloured in green, M2 in yellow (PDB accession number 3UON), M3 (PDB accession number 4U15, chain A) in orange, and M4 (chain A) in blue. Root mean squared deviations for the alignment (excluding T4L fusions) of M1, M2, and M4 versus the M3 receptor are 0.86 Å, 0.81 Å, and 0.62 Å, respectively. The ligand, tiotropium, for the M4 receptor is shown as sticks and coloured according to element: carbon, light blue; oxygen, red; nitrogen, dark blue; sulfur, yellow. **b**, **c**, Comparison of the views from **(b)** the extracellular side

S^{4.53} (Extended Data Fig. 3d). More interestingly, the M4 receptor was crystallized with an intact ionic lock (Extended Data Fig. 3e) a feature uncommonly seen in other GPCRs and not present in the other muscarinic structures. It is important to note that the observed differences in the intra- and extracellular sides of the receptor occur in regions that are solvent accessible or are involved in crystal packing interactions, which could contribute to the observed perturbations between subtypes; however, none of the crystal packing interactions grossly affect the structure or the core of the receptor.

Like the inactive M3 receptor, the M1 and M4 receptors were crystallized in complex with the inverse agonist, tiotropium, and this binding site is buried deep within the transmembrane core (Fig. 1d). The binding pose of tiotropium and surrounding residues between these three structures is nearly identical (Fig. 1d–f), which is not surprising given the near absolute conservation of residues lining the orthosteric site in the muscarinic family (Extended Data Fig. 2). However, this high degree of sequence conservation does not preclude the possibility of differences in tertiary structure with respect to the orthosteric site. Indeed, one surprising difference is a change in the rotamer of D112^{3.32} of the M4 receptor (Fig. 1 f, g); a residue that is conserved throughout

and **(c)** the intracellular side. **d**, M1 and M4 residues involved in tiotropium binding are shown as sticks (several residues are omitted for clarity). The black dashed line indicates a bidentate hydrogen bond between N^{6.52} and tiotropium. **e**, Superposition of tiotropium from the M1, M3, and M4 structures and QNB from the M2 structure. The arrow indicates the main structural difference between tiotropium and QNB. **f**, Comparison of the orthosteric binding site of the M1–M4 receptors with orthosteric site residues shown as sticks. **g**, The rotameric change of D112^{3.32} is stabilized by a network of hydrogen bonds.

the biogenic amine GPCRs and serves as the counter ion for positively charged neurotransmitters²⁷. This rotameric change points D112^{3.32} away from tiotropium and is accompanied by slight movements of Y439^{7.39} and Y443^{7.43}, allowing them to form a network of hydrogen bond interactions between D112^{3.32} and S85^{2.57}, W108^{3.28}, Y439^{7.39}, and Y443^{7.43}, which is distinct from the M1, M2, and M3 muscarinic receptor structures (Fig. 1g).

Further comparison of the M1, M3, and M4 tiotropium-bound structures with the M2 receptor, which was crystallized with the structurally similar inverse agonist, QNB, also revealed considerable differences around residues D^{3.32}, Y^{7.39}, and Y^{7.43}. These three residues surround the amine group, which is slightly more bulky for QNB than tiotropium (Fig. 1e–g). Indeed, previous mutagenesis studies²⁸ on the M1 receptor revealed ligand-specific changes in binding affinities of NMS and QNB upon mutation of Y^{7.39} and Y^{7.43} to alanine. For the ligand NMS, which has a structurally similar tropane ring to tiotropium, a 25- and 48-fold loss of binding affinity was observed for the Y^{7.39} and Y^{7.43} mutations, respectively, whereas little effect was observed for QNB. This suggests a potential role for these two residues in stabilizing different inactive-state conformations with QNB potentially making compensatory

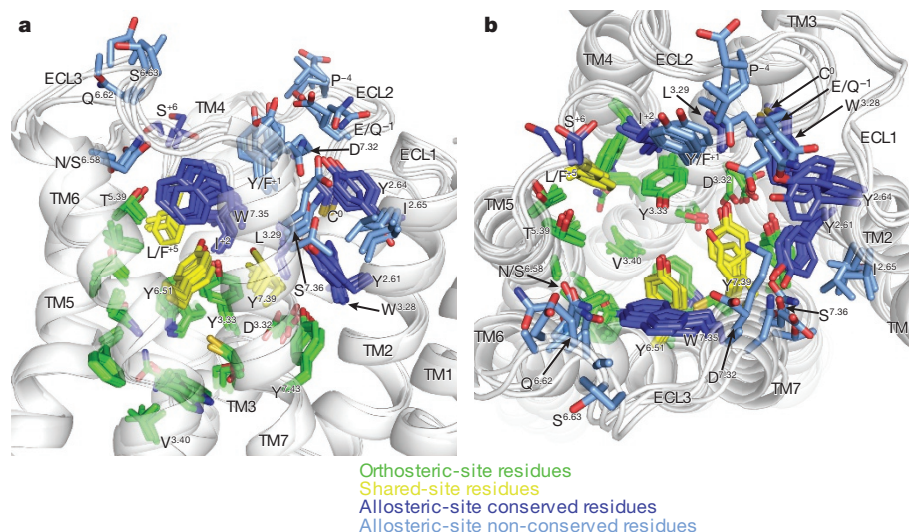

Figure 2 | Comparison of orthosteric and allosteric binding site residues across the M1–M4 receptors. a, b, The M1–M4 receptors are aligned to the M3 muscarinic receptor (PDB accession number 4U15, chain A) and are shown as grey coloured cartoons with views from the (a) membrane and (b) extracellular side. Residues in ECL2 are numbered relative to the position of the disulfide-bonded cysteine. Carbon atoms are coloured by site with the orthosteric residues

in green, dark blue for allosteric conserved residues, light blue for allosteric non-conserved residues, and yellow for residues that contribute to both sites. Oxygen atoms are coloured red, nitrogen blue, and sulfur yellow. Non-conserved residues are labelled according to either the most common residue or by the residue at the M4 receptor. Residues K^{6.62} (M1), D^{6.63} (M1), and S^{6.63} (M3) are shown as alanine owing to a lack of electron density on the side chains.

interactions unavailable to NMS. The fact that the orthosteric site of the M4 receptor is in some ways closer to the M1 than the M2 subtypes may also allow some rationalization of the relative subtype selectivity for canonical orthosteric antagonists such as pirenzepine, which has long been known to have a rank order potency of M1 > M4 > M3 > M2 (ref. 29). We performed induced fit docking (IFD) experiments of the antagonist into the inactive-state structures of the M1–M4 receptors. The overall poses for pirenzepine were very similar, with slight variability in the positioning of the methylpiperazine moiety (Extended Data Fig. 4a). However, there were still distinct differences in the orientation of residues D^{3.32} and Y^{7.39} between the M1, M3, and M4 subtypes versus the M2 receptor, with D^{3.32} oriented towards and Y^{7.39} away from the methylpiperazine group in the M2 IFD (Extended Data Fig. 4b). These differences should be interpreted with caution, as it is possible they reflect a restricted sampling in the IFD protocol, and may not be reflective of a genuine M2 specific preference. Nevertheless, these results suggest that the differences in positions of D^{3.32} and Y^{7.39}, which surround the methylpiperazine group, could contribute to the marked difference in potency for pirenzepine between the M1 and M2 subtypes²⁹.

Allosteric binding and cooperativity

A comparison of all four solved muscarinic receptor structures illustrates the strikingly high degree of conservation of the residues constituting the orthosteric site (Fig. 2, green), thus providing a structural basis for the difficulty in achieving subtype selectivity when targeting this region. In contrast, muscarinic receptors possess a large extracellular vestibule that contains residues contributing to an allosteric site. As shown in Fig. 2 (blue), comparison of these residues reveals a striking divergence between subtypes, owing to differences in amino-acid composition (Extended Data Fig. 2) and likely additional tertiary structure changes that arise as a consequence of the dynamic nature of the extracellular loop regions. Also shown in Fig. 2 (yellow) are residues that have been previously suggested to form the 'roof' of the orthosteric site and 'floor' of the allosteric site^{20,30}. These 'shared' residues show an intermediate degree of tertiary structure divergence between subtypes compared with the orthosteric and allosteric site residues, and are conserved among all five subtypes with the exception of the M2 receptor where L in ECL2 is replaced by F.

Comparison of the electrostatic surface potential of each receptor (Fig. 3) also reveals distinct differences in both the shape and charge

distribution of the allosteric site and can explain why some of the best-studied muscarinic receptor allosteric modulators are cationic compounds³¹. For example gallamine³², a prototypical negative allosteric modulator of muscarinic receptors, has a binding potency order of M2 > M1, M4 > M3, M5 (ref. 33). The acidic EDGE sequence (Fig. 3b) of the M2 receptor has been shown to be important for gallamine affinity and cooperativity; indeed, replacement of M1 residues LAGQ with the EDGE (Fig. 3b) significantly improved gallamine affinity at the M1 receptor³³.

Interestingly, inspection of our M4 receptor data also revealed that the precipitant, polyethylene glycol 300 (PEG 300), is able to occupy the allosteric binding site of the inactive-state receptor (Extended Data Fig. 5), a finding consistent with the recent structure of the M3-mT4L receptor²⁶. Surrounding the PEG 300 molecule are residues that form the allosteric site from the top regions of TM2, TM3, and TMs 5–7 (Extended Data Fig. 5b). Furthermore, PEG 300 sits immediately above the aromatic cage composed of Y113^{3.33}, Y416^{6.51}, Y439^{7.39}, and Y443^{7.43} (Extended Data Fig. 5a). These residues have been implicated in regulating the dissociation of antagonists from the orthosteric binding site³⁴, and we confirmed the ability of PEG 300 to act as an allosteric modulator in its own right through its ability to retard the dissociation of [³H]NMS in a concentration-dependent manner with a calculated apparent affinity of approximately 10 mM for the [³H]NMS-occupied M4 receptor (Extended Data Fig. 5c, d).

Our finding above illustrates an inherent difficulty in obtaining inactive-state structures with prototypical negative allosteric modulators bound in the open muscarinic extracellular vestibule, as PEG 300 is a required precipitant and is present at concentrations of over 1.0 M. However, a recent breakthrough was the solution of the active-state structure of the related M2 muscarinic receptor bound to a high efficacy agonist, iperoxo, in the absence or presence of the PAM, LY2119620, which preferentially bound in a more tightly closed vestibule that arises in the active-state³⁵. Because the M4 receptor is most closely related to the M2 subtype, and M4 receptor PAMs are highly pursued as novel therapeutic agents^{4,36}, we undertook a combined mutagenesis and molecular modelling study to complement our structural work and gain additional insights into mechanisms governing positive allosteric modulation at this muscarinic receptor subtype.

We investigated the interaction between the well-characterized PAM, LY2033298 (refs 13–15, 20, 21), and the cognate agonist, acetylcholine.

Figure 3 | Electrostatic and surface properties of the different muscarinic receptor structures. **a**, Electrostatic potentials ($+5kT/e$ in blue and $-5kT/e$ per electron in red) mapped on the surfaces of the M1–M4 receptor structures calculated at pH 7.0 using the programs PDB2PQR^{43,44} and APBS⁴⁵. **b**, Residues in ECL2 that make up the EDGE sequence at the M2 receptor and the corresponding regions at the other subtypes are shown as sticks. Negatively charged residues in the sequence alignment are coloured red.

On the basis of the recent structure of the active M2 receptor bound to the LY2033298 congener, LY2119620 (refs 35, 37, 38), it is likely that such PAMs bind to an essentially pre-formed closed state of the extracellular vestibule. As such, residues whose mutation might alter the cooperativity between acetylcholine and LY2033298 fall into three general categories: (1) those that make tighter contacts with the ligands in the closed state than the open state; (2) those that are immobilized by the binding of either ligand, such that the entropic cost is paid by the first binding event; (3) non-ligand-contact residues that alter the free energy of activation of the receptor and thus the open to closed transition. We chose to focus on residues within and between the extracellular vestibule and orthosteric sites, which are likely to reflect the first two categories; mutagenesis of non-contact residues that govern the free energy of receptor transitions are beyond the scope of the current work.

Because prior mutagenesis studies suggested a role for aromatic residues in receptor interaction with LY2033298, we generated alanine mutations of selected aromatic residues near the top of the receptor and applied an allosteric ternary complex model to the data (Methods) to determine the effect of each mutation on the affinity of acetylcholine (K_A) or LY2033298 (K_B) for the free receptor and the magnitude of positive cooperativity (α) between the two ligands. We also chose to investigate selected (non-aromatic) residues that line the proximal and distal ends of ECL2, given the important role this region plays in the binding of modulators to the extracellular vestibule^{18,39–41}. The results of these experiments are summarized in Supplementary Tables 2–4 and include prior mutagenesis results from our laboratory for the same set of ligands. To rationalize our findings, we used the recent active state M2 receptor structure as a template to generate a homology model of the M4 receptor bound to acetylcholine and LY2033298, and compared this with our inactive state crystal structure (Fig. 4 and Extended Data Fig. 6).

The most dramatic effect on the affinity of the PAM was noted upon mutation of W435^{7.35} at the top of TM7, with a complete loss in LY2033298 binding, similar to our previous observations²¹ upon alanine substitution of F186^{ECL2} (Fig. 5, Extended Data Fig. 7 and Supplementary Tables 3 and 4). Alanine mutations of residues Y113^{3.33}, Y416^{6.51}, and Y439^{7.39}, which form the roof of the orthosteric site, led to significant decreases in cooperativity. A slight increase in modulator affinity and significant decrease in cooperativity was also noted with mutation of Y89^{2.61}, together with our prior identification of residues W108^{3.28} and L109^{3.29} as likely contributors to the PAM binding

Figure 4 | Model of an active M4 receptor bound to acetylcholine and LY2033298. **a**, Comparison of the M4•tiotropium receptor structure (blue) versus an active-state model (orange) bound to acetylcholine and LY2033298 on the basis of the active M2•iperoxo•LY2119620 structure (PDB accession number 4MQT) as viewed from the membrane. The active M4 model was aligned to the M4•tiotropium structure (chain A, excluding T4L) with a root mean squared deviation of 0.9 Å. **b**, **c**, Cross-sectional views of the (b) allosteric site and (c) orthosteric site as viewed from the extracellular side with a 90° rotation relative to the membrane from **a**. Residues surrounding each site are shown as sticks (several removed for clarity). Acetylcholine and LY2033298 are shown as (a) spheres or (b, c) sticks and coloured according to element: carbon, cyan; oxygen, red; nitrogen, blue; sulfur, yellow; chlorine, green. Acetylcholine is in the *trans* conformation and aligns in a similar pose to iperoxo (c, transparent yellow sticks).

pocket²⁰. Comparison of our inactive state structure to the active state model now provides a mechanistic rationale for our findings, specifically a contraction of the extracellular vestibule that results predominantly in an inward movement of N423^{6.58}, F186^{ECL2}, and W435^{7.35} allowing π -stacking interactions to occur with the modulator in the active state (Fig. 4b). For the acetylcholine-binding pocket, there is a contraction of the pocket mediated by an inward movement of the top of TM6 to accommodate the large difference in size between acetylcholine and tiotropium resulting in significant movement of residues Y416^{6.51}, N417^{6.52}, W413^{6.48}, and Y439^{7.39} (Fig. 4c). Additionally, D112^{3.32} is reoriented to interact with the choline head-group of acetylcholine, and is no longer stabilized by the same hydrogen bond network that is seen in the inactive state (Fig. 1g).

Importantly, mapping of the amino-acid residues that significantly affect the cooperativity between acetylcholine and LY2033298 upon mutation also identified, for the first time, a network that appears to link the allosteric and orthosteric sites, involving the interface between TMs 2, 3, 6, and 7, and extending along the top of ECL2 (Fig. 5; orange coloured residues); this network is consistent with views of allosteric modulation that propose a preferred energetic link between orthosteric and allosteric sites⁴² but, to our knowledge, has never been directly mapped before in a GPCR. Interestingly, a comparison of the side-chain locations between the inactive M4 structure and active M4 model for residues in the allosteric network reveals that the majority of residues at the TM2/3/7 interface that contribute to cooperativity are not predicted to undergo appreciable movement between states, whereas comparison of residues further away from the interface (F186^{ECL2}, Y416^{6.51},

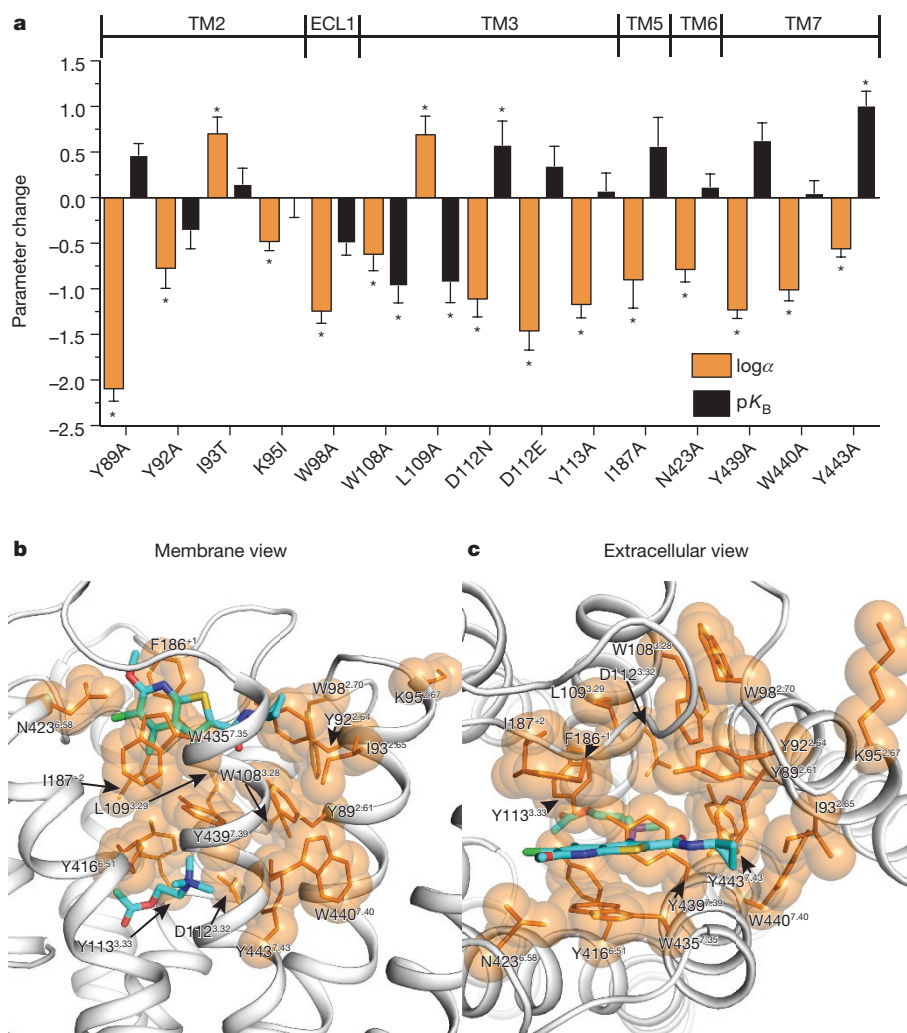

Figure 5 | A cooperativity network at the M4 receptor. a, Changes in either LY2033298 binding affinity (ΔpK_B , coloured black) or cooperativity ($\Delta \log \alpha$, coloured orange) relative to wild-type M4 are shown for each mutation. Data represent the mean \pm s.e.m. from at least three experiments performed in duplicate. Statistical differences between pharmacological parameters at wild-type versus mutant M4 receptors are indicated by asterisks and were determined by one-way analysis of variance with Dunnett's post hoc test, where $P < 0.01$ (Supplementary

Table 3) or $P < 0.05$ (for previously determined mutations; Supplementary Table 4) were considered statistically significant. Cooperativity and binding values for F186⁺¹ and W435^{7,35} were not determined owing to a lack of LY2033298 binding (see Supplementary Tables 2–4). **b**, **c**, Residues from **a** were mapped onto the M4 active-state model and coloured as orange sticks with translucent spheres with views from **(b)** the membrane and **(c)** the extracellular side. LY2033298 and acetylcholine are shown as sticks and coloured the same as in Fig. 4.

N423^{6,58}, and W435^{7,35}) are predicted to move significantly between the two states (Extended Data Fig. 8). The TM2/3/7 interface, which forms part of the hydrophobic core of the receptor, may act as a hinge mediating conformational rearrangements in the extracellular vestibule between the inactive (open extracellular vestibule) and active (closed extracellular vestibule) states of the receptor. Disruption of this hinge by mutagenesis alters the packing interactions within the interface and might change the energetic barrier between the open and closed conformations of the receptor leading to either an increase or decrease in PAM cooperativity. Thus, binding of a PAM to the allosteric site might stabilize the conformation of the allosteric network residues that are otherwise found in a more dynamic state. Presumably, structures of the inactive state and active M4 model described here represent the lowest energy conformations, as they were obtained using crystallography, or are based on the X-ray structures of the active M2 receptor³⁵ (Extended Data Fig. 8).

Another noteworthy feature of LY2033298 is that it is selective towards the M4 receptor versus the M1 receptor when tested against acetylcholine¹⁵. This difference in selectivity could arise either through differential binding affinities of LY2033298 or through a difference in the cooperativity between LY2033298 and acetylcholine between the two subtypes (Extended Data Fig. 9).

Conclusions

Muscarinic receptors remain important drug targets, and designing molecules to selectively target the orthosteric binding site has proved challenging, as highlighted by the lack of prominent differences between the receptor subtypes. Alongside the previously determined M2 and M3 structures, the M1 and M4 structures presented here now offer a near complete view of the inactive state of this important sub-family of GPCRs. Excitingly, comparison of these structures clearly reveals a divergence in residues lining the allosteric site, highlighting the importance of this region for designing selective drugs. Moreover, our enriched structure–function analysis of the M4 receptor indicates that it is possible to combine crystal structure and mutagenesis data to uncover new insights into GPCR allosteric modulation, and our results point to the TM2/3/7 interface as a network for further studies on the mechanistic basis of allostery at class A GPCRs. Together with the recent solution of the inactive M2 and M3 receptors, as well as the active and PAM-bound M2 receptor, our study has contributed to an emerging picture of mechanisms of allostery at a therapeutically important receptor family that may facilitate the design of novel agents targeting a variety of CNS disorders while avoiding peripheral off-target effects.

Acknowledgements We thank L. Lopez for generating initial M4 homology models. This work was funded by Program Grant APP1055134 of the National Health and Medical Research Council (NHMRC) of Australia (A.C., P.M.S.). Portions of this work were supported by a Lilly Research Award Program grant. W.I.W. and B.K.K. were supported by the Mathers Foundation. A.C. is a Senior Principal, and P.M.S. a Principal, Research Fellow of the NHMRC. GM/CA @ APS has been funded in whole or in part with federal funds from the National Cancer Institute (Y1-CO-1020) and the National Institute of General Medical Science (Y1-GM-1104). Use of the Advanced Photon Source was supported by the US Department of Energy, Basic Energy Sciences, Office of Science, under contract number W-31-109-ENG-38.

Author Contributions D.M.T. performed cloning, protein expression, purification, crystallization, data collection, structure refinement, and radioligand binding assays on the M4 receptor. D.F. purified and crystallized the M1 receptor. B.S. performed data collection and structure refinement on the M1 receptor. K.L., V.N., and D.M.T. performed mutagenesis and radioligand binding studies that examined the effects of amino-acid substitutions on ligand pharmacology. C.C.F., M.G.B., and D.E. provided the pirenzepine IFD and active-state M4 homology model. P.B. generated the active-state model of the M1 receptor. T.S.K. supervised the M1 muscarinic receptor production and purification. W.I.W. supervised structure refinement. B.K.K., P.M.S., and A.C. provided overall project supervision. D.M.T. and A.C. wrote the manuscript.

Author Information Atomic coordinates and structure factors for the M1 and M4 receptors, respectively, have been deposited in the Protein Data Bank (PDB) under accession numbers 5CXV and 5DSG. Reprints and permissions information is available at www.nature.com/reprints. The authors declare competing financial interests: details are available in the online version of the paper. Readers are welcome to comment on the online version of the paper. Correspondence and requests for materials should be addressed to P.M.S. (patrick.sexton@monash.edu), B.K.K. (kobilka@stanford.edu) or A.C. (arthur.christopoulos@monash.edu).

METHODS

No statistical methods were used to predetermine sample size. The experiments were not randomized. The investigators were not blinded to allocation during experiments and outcome assessment.

M1 and M4 receptor expression and purification. The human M4 muscarinic receptor gene (<http://www.cdna.org>) was cloned into a modified pFastBac1 vector to give a receptor containing an N-terminal Flag epitope tag and a carboxy (C)-terminal 8 × histidine tag. Residues 226–389 of ICL3 were removed and replaced by a minimal Cys-free T4 lysozyme fusion protein²⁶. The human M1 muscarinic receptor gene was also cloned into the modified pFastBac1 vector, and residues 219–354 of ICL3 were removed and replaced by a Cys-free T4 lysozyme fusion protein. Both fusion proteins were expressed using the Bac-to-Bac Baculovirus Expression System (Invitrogen) in *Sf9* cells. Cells were infected at a density of 4.0×10^6 to 5.0×10^6 cells per millilitre, treated with 10 μ M atropine, and harvested at 60 h. Receptor was solubilized and purified in the presence of tiotropium as previously described for the M3 (ref. 22) receptor using Ni-NTA chromatography, Flag affinity chromatography, and size-exclusion chromatography. The N terminus of the M4 receptor was removed by cleavage with HRV 3C protease at a concentration of 2% (w/w) during concentration of the receptor before size-exclusion chromatography (~2 h at 4 °C). After size-exclusion chromatography, purified receptor was concentrated to 85 absorbance units (~50 mg ml⁻¹) and flash frozen in small aliquots using liquid nitrogen.

Pharmacology of crystallization constructs. *Sf9* cells expressing wild-type M4 or M4-mT4L receptor, as described above, were pelleted and washed with PBS three times for 1 h each to remove any bound atropine. Cells were resuspended in binding buffer (10 mM HEPES pH 7.5, 100 mM NaCl, and 10 mM MgCl₂) and flash frozen with liquid nitrogen. Saturation binding assays were performed using approximately 20,000 cells per well with 9 different concentrations of [³H]NMS in a total volume of 0.5 ml for 3 h at 37 °C. Competition binding assays with acetylcholine and tiotropium were performed in the presence of a fixed concentration of [³H]NMS over 10 different concentrations of ligand for 3 h at 37 °C. Non-specific binding was measured in the presence of 10 μ M atropine, and reactions were harvested by rapid filtration through GF/B filters. Data were analysed using Prism 6.0d. Similar methods were applied for binding assays using wild type M1 and M1-T4L, except that [³H]QNB was used as the radioligand.

Crystallization. Purified M1-T4L•tiotropium and M4-mT4L•tiotropium were crystallized using lipid cubic phase technology. Each receptor was reconstituted by mixing the protein solution into 10:1 (w/w) monoolein:cholesterol (Sigma) in 1:1.5 parts w/w protein:lipid ratio using the two-syringe method²⁴. For the M1 receptor, samples of 50 nl (20–40 nl for M4) were spotted onto 96-well glass plates and overlaid with 800 nl (600 nl for M4) of precipitant solution for each well using a Gryphon LCP (Art Robbins Instruments). Glass plates were then sealed using a glass cover film and incubated at 20 °C. Initial crystals for the M1 receptor formed after 24 h in conditions containing 33% PEG 300, 100 mM sodium acetate, and 100 mM Bis-Tris Propane (pH 8.0). For the M4 receptor, initial crystals formed after 24 h in conditions containing 25–40% PEG 300, 50–100 mM EDTA (pH 8.0), and 100 mM MES (pH 5.5–6.5). M1 and M4 crystals were harvested using mesh grid loops (MiTeGen) and stored in liquid nitrogen before use.

Data collection, processing, and structure determination. X-ray diffraction data were collected at the Advanced Photon Source at Argonne National Laboratories at GM/CA beamline 23ID-D. Crystals were located by initial rastering using an 80 μ m by 30 μ m beam with fivefold attenuation and 1 s exposure. Regions that contained strong diffraction were then sub-rastered using a 10 μ m collimated beam with fivefold attenuation. Data were then collected with the 10 μ m beam using no attenuation with 1–2 s exposures and 1 degree oscillations. To prevent radiation damage, data were collected in wedges of 3–10° before moving onto either a different site on the same crystal or a new crystal. Diffraction data were processed using HKL2000 (M1 receptor) or XDS⁴⁶ (M4 receptor) and statistics are summarized in Extended Data Table 1. Both structures were solved by molecular replacement using Phaser⁴⁷. For the M1 receptor, the inactive M3 structure²² (PDB accession number 4DAJ) was split into its receptor and T4L components and used as corresponding search models. The refinement was performed using Refmac5 (ref. 48) with manual building in Coot⁴⁹. For the M4 receptor, the inactive M2 structure²³ (PDB accession number 3UON) and the inactive M3-mT4L²⁶ (PDB accession number 4U15) were used as search models for the receptor and mT4L fusion domains, respectively. The resulting model was completed by iterative refinement in Phenix⁵⁰ and manual building with Coot⁴⁹. MolProbity⁵¹ was used for structure validation, and figures were prepared using PyMol⁵². Final refinement statistics are reported in Extended Data Table 1.

Induced fit docking of pirenzepine. The inactive state structures of M1, M2, M3 (PDB 4U15, chain B), and M4 (chain A) receptors were processed by the protein preparation wizard of the Schrodinger 2014-2 suite⁵³, after deleting the lysozyme insertion region. Missing side chains were added by Prime and hydrogens refined

by minimization with the OPLS2.1 force field. Binding grids were defined using the default settings in Glide, centring the grid on the crystallized orthosteric ligand in each case. The PEG ligand in the extracellular vestibule of M3 and M4 receptors was deleted before grid generation. The ligand, pirenzepine, was treated with ligprep software to generate initial protonated 3D structures. Compound structures were docked using the induced fit docking protocol with default settings, which involves the use of the OPLS_2005 force field to refine residues around poses docked by Glide SP, followed by redocking into the generated receptor conformations, also with Glide SP. The poses with the lowest induced fit score were selected. This scoring function takes into account an estimate of the protein conformational penalty along with a protein–ligand interaction docking score.

Molecular modelling of active M4 receptor. A homology model of a human active-state M4 receptor was constructed using the Prime program implemented in Maestro version 2014.1 from Schrodinger. The crystal structure of the M2 receptor with an orthosteric and allosteric agonist bound (PDB accession number 4MQT) was used as a template to build the M4 model. The M2–M4 sequence alignment generated by Prime needed no adjustment owing to the overall significant sequence homology between the two isoforms. The initial M4 receptor model was built with the allosteric ligand (LY2119620) present in the M2 crystal structure bound in the M4 allosteric site and with iperoxo bound in the orthosteric site (as also present in the M2 structure). The binding mode of LY2119620 in M4 was used as a guide to manually dock LY2033298 into the M4 allosteric binding site. In addition, iperoxo from the M4 model was manually modified into acetylcholine (ACh). The M4-ACh-LY2033298 complex was then subjected to 500 steps of energy minimization (MacroModel implemented in Maestro 2014.1 from Schrödinger⁵³) to optimize key interactions in the binding sites. The resulting model of ACh and LY2033298 bound to M4 was used in subsequent modelling studies described in this paper.

Molecular modelling of active M1 receptor. The active state of the M1 receptor was modelled on the basis of the active state structure of M2 bound to iperoxo (PDB accession number 4MQT), using the automated protein structure homology modelling web server Swiss-Model^{54,55}. The nanobody structure was removed and the resulting coordinates were used as a template to model the M1 primary sequence without intracellular loop 3 residues (residues 213–240). The model was built using Promod-II, minimized by steepest descent energy minimization using a GROMOS96 force field and the quality was assessed by the QMEAN scoring function. ACh and LY2033298 were docked in the M1 homology model using Swiss-Dock⁵⁶, using steric and chemical considerations such as shape, charge complementary, and keeping the protein structure constant. The top-scoring clusters were evaluated manually on the basis of chemical and steric considerations to pick the favourable pose. Owing to static docking, the top four ACh poses did not affect the docking results for LY2033298. For ACh, the selected pose is in the trans conformation similar to the M4•ACh•LY2033298 model. Finally, the structures with the ligand were energy minimized using Chimera with standard Steepest Descent and Conjugate Gradient steps.

Receptor mutagenesis and generation of cell lines. DNA encoding the human M4 mAChR with a triple HA²⁰ or cmcy²¹ tag at its N terminus was subjected to QuikChange site-directed mutagenesis (Stratagene) to generate M4 mAChR sequences with the desired amino-acid substitutions. DNA constructs in pEF5/ft/V5 (Invitrogen) were stably expressed in FLP-In-CHO cells (Invitrogen), which were maintained in high-glucose Dulbecco's modified Eagle's medium containing 10% FBS, 16 mM HEPES, and 400 μ g ml⁻¹ hygromycin B. Mycoplasma testing was performed regularly on cell lines using the MycoAlert™ kit (Lonza); cell lines were mycoplasma-free before experiments were conducted.

Radioligand binding assays. Cell membranes were prepared as described previously^{14,57}. [³H]QNB affinity (K_A) at the M4 WT receptor and mutants was determined by saturation binding assays, performed by incubating varying concentrations of [³H]QNB with 10–100 μ g of membranes at 37 °C for 1 h, in a final volume of 0.5–1 ml binding buffer (20 mM HEPES, 100 mM NaCl, and 10 mM MgCl₂ at pH 7.4).

Radioligand inhibition binding assays were performed by co-incubating 10–100 μ g of membranes with a K_A concentration of [³H]QNB (determined in saturation assays, Supplementary Table 2) and varying concentrations of the non-radiolabelled test compound in 0.5–1 ml binding buffer in the presence of the guanine nucleotide, GppNHp (100 μ M), which was used to promote receptor/G-protein uncoupling. These experiments determined the concentration of ACh that inhibited 20% [³H]QNB binding, defined as the 20% inhibitory concentration (IC₂₀), which was used in subsequent interaction studies between [³H]QNB, ACh, and LY2033298. These experiments were performed by co-incubating 10–100 μ g of membranes, an IC₂₀ concentration of ACh, and a K_A concentration of [³H]QNB with increasing concentrations of LY2033298 in binding buffer containing GppNHp (100 μ M). The reaction was left to reach equilibrium for 3 h at 37 °C. For all experiments, non-specific binding was defined in the presence of

10 μ M atropine, total binding was determined in the absence of the test ligand, and vehicle effects were determined with 0.1% dimethylsulfoxide (DMSO). The assays were terminated by vacuum filtration through GF-B glass fibre filters, which were washed three times with ice-cold 0.9% NaCl. [3 H]QNB radioactivity was measured using a Packard 1600 TR liquid scintillation beta counter. Owing to a lack [3 H]QNB binding, affinity data for W164A^{4,57} were determined from functional pERK1/2 experiments performed as previously described^{20,21}.

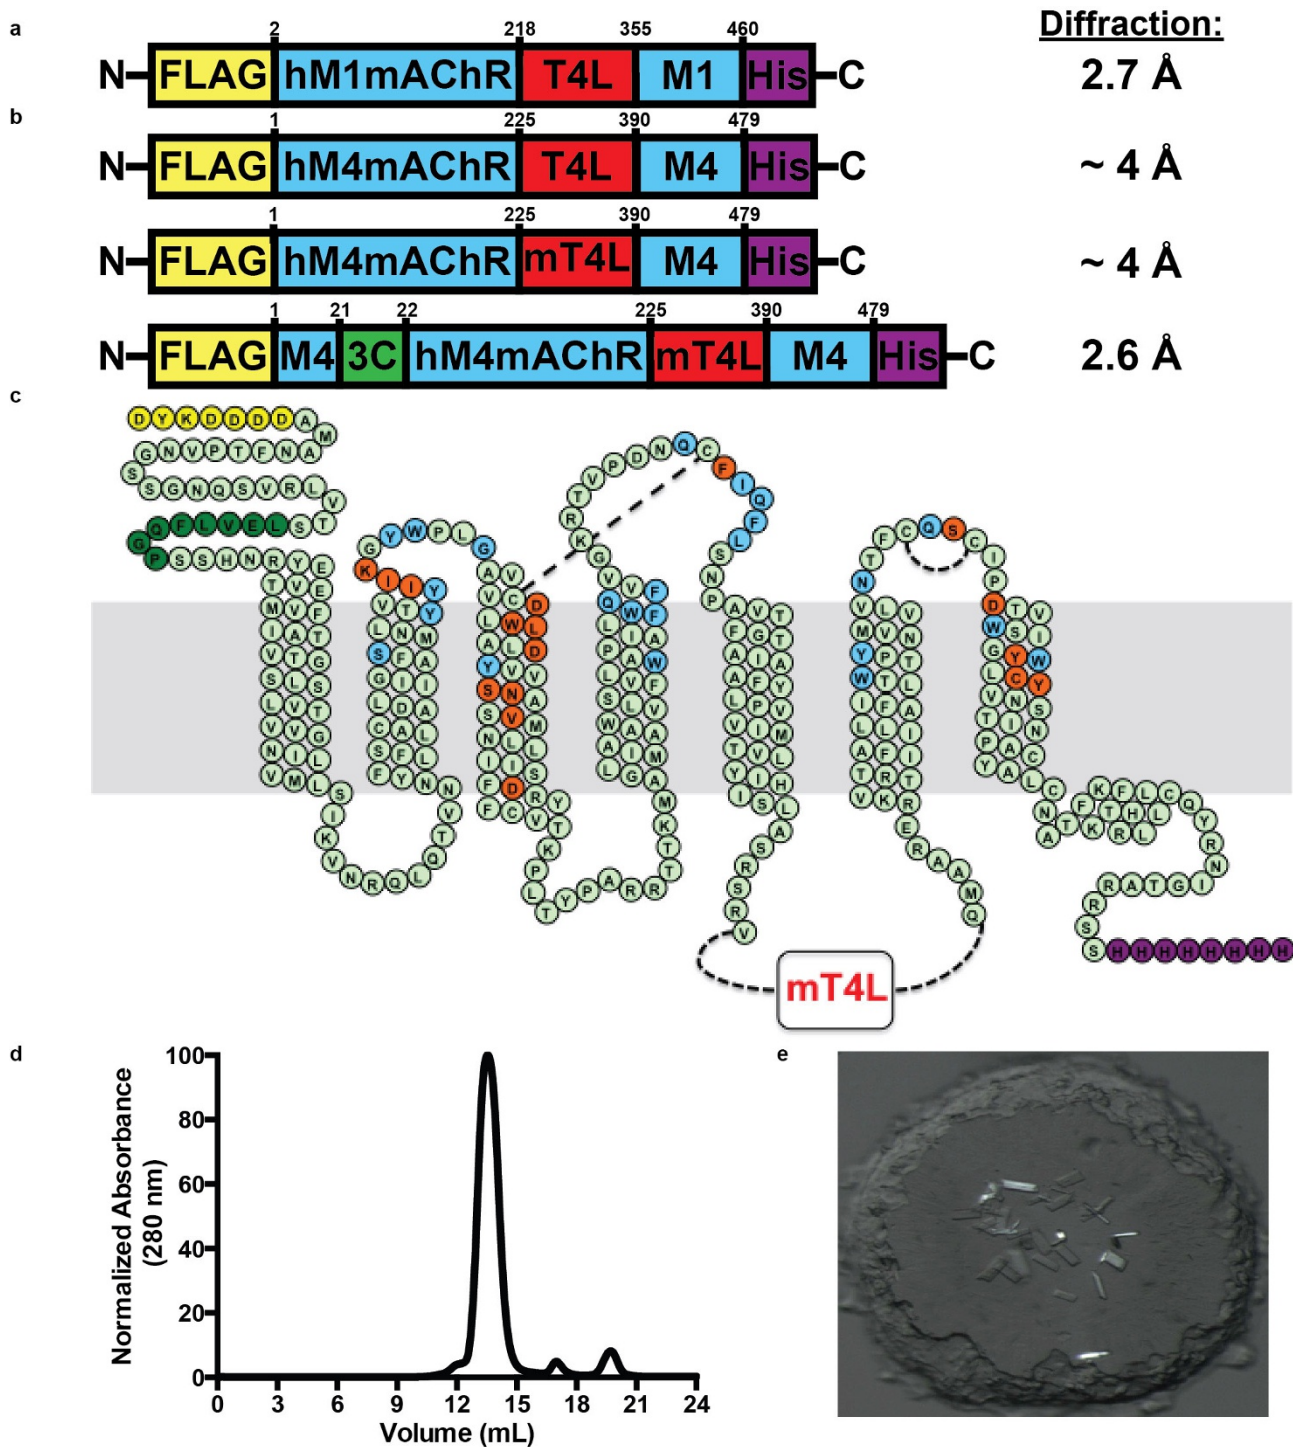

Data analysis. Data were analysed using Prism (GraphPad). For radioligand saturation binding, non-specific and total binding data were analysed as described previously⁵⁸. Inhibition binding curves between [3 H]QNB and ACh were fitted to a one-site binding model⁵⁸. Interaction experiments between [3 H]QNB, ACh, and LY2033298 were fitted to the following allosteric ternary complex model^{20,21,59}:

$$Y = \frac{B_{\max} [A]}{[A] + \left(\frac{K_A K_B}{\alpha' [B] + K_B} \right) \left(1 + \frac{[I]}{K_I} + \frac{[B]}{K_B} + \frac{\alpha [I][B]}{K_I K_B} \right)}$$

where Y is the specific radioligand binding, B_{\max} is the total number of receptors, $[A]$, $[B]$, and $[I]$ are the concentrations of radioligand, allosteric modulator, and unlabelled orthosteric ligand, respectively, K_A , K_B , and K_I are the equilibrium dissociation constants of the radioligand, allosteric modulator, and unlabelled orthosteric ligand, respectively, and α' and α are the cooperativity factors between allosteric modulator and the radioligand or unlabelled orthosteric ligand, respectively. The value of α' was taken as 1 when the binding of [3 H]QNB changed by less than 10% at 10^{-5} M LY2033298 relative to zero LY2033298, and was fixed as such for all analyses. Otherwise, the value of α' was determined using a global fit to the allosteric ternary complex model. Statistical differences between pharmacological parameters at wild-type versus mutant M4 receptors were determined by one-way analysis of variance with Dunnett's post hoc test, where $P < 0.01$ was considered statistically significant.

Extended Data Figure 1 | Crystallization construct design, purification and crystallization. **a, b,** Crystallization constructs used for the (a) M1 receptor and (b) M4 receptor. All constructs contain an N-terminal Flag epitope (yellow), C-terminal histidine tag (purple), and a T4L lysozyme fusion protein (red). For the M4 receptor, initial constructs diffracted out to 4 Å; however, the diffraction data appeared to suffer from a lattice translocation disorder and were unsolvable. The final crystallization construct contained a shortened N terminus with an HRV 3C cleavage

site, shown in dark green, and a minimal T4 lysozyme fusion (mT4L)²⁶, shown in red. **c,** Snake-plot diagram of the best diffracting M4 mAChR construct coloured according to **a**. Residues coloured blue are single-point mutations from this study, and residues coloured orange are previously studied mutations^{20,21}. **d,** Size-exclusion chromatography trace of purified monodispersed M4-mT4L bound to tiotropium. **e,** Crystals of M4-mT4L obtained in lipidic cubic phase and observed under circularly polarized light.

Extended Data Figure 2 | Sequence conservation across the muscarinic receptor subfamily. **a–c**, The sequence alignment of the human M1–M5 receptors (**d**) was determined on the ConSurf server to calculate amino-acid conservation scores^{60,61}. Conservation scores for each residue were mapped^{62,63} onto the M4 structure and coloured as a gradient from blue (highly conserved) to red (least conserved) with views from the (**b**) extracellular and (**c**) intracellular sides. The radius of the cartoon increases as the residues at each position become more poorly conserved. Tiotropium and PEG 300 from the M4 structure are shown as spheres and coloured with carbon in white, oxygen in red, nitrogen in blue, and sulfur

in yellow. **d**, Amino-acid sequences of the human M1–M5 receptors were aligned using the ClustalW2 server⁶⁴. Alpha helical regions are shown as blue boxes as determined by the consensus of the M1–M4 structures. The most conserved residue in each TM (X.50) is in bold lettering. Regions of the N terminus, C terminus, and ICL3 regions are removed for space and clarity. Insertion points of the T4 lysozyme fusion proteins between TM5 and TM6 are underlined with bold lettering. Residues from the orthosteric binding-site are highlighted in red and allosteric binding-site residues in blue. Residues that contribute to both sites are coloured in yellow.

Extended Data Figure 3 | Distinct structural features for the M1 and M4 receptors. The receptors shown are aligned and coloured as in Fig. 1. **a, b**, The M1 receptor was crystallized with the Flag peptide (DYKDDDD; coloured cyan sticks) co-bound on the cytoplasmic surface. Residues of the M1 receptor within 4 Å of the Flag peptide are shown as magenta coloured sticks with views from the (a) membrane and (b) cytoplasmic side. **c**, The

linkage between TM7 and helix 8 of the M1 receptor undergoes a bend starting with a change in rotamer of residue Y^{7.53}, which may be a result of perturbations in TM6 due to the Flag peptide. **d**, The M1-N110Q^{3.37} mutation causes a slight bulge in TM4 due to the loss of a hydrogen bond with S^{4.53}. **e**, Chain B of the M4 receptor has an intact ionic lock with R^{3.50} forming hydrogen bonds with T^{6.34} and E^{6.30}.

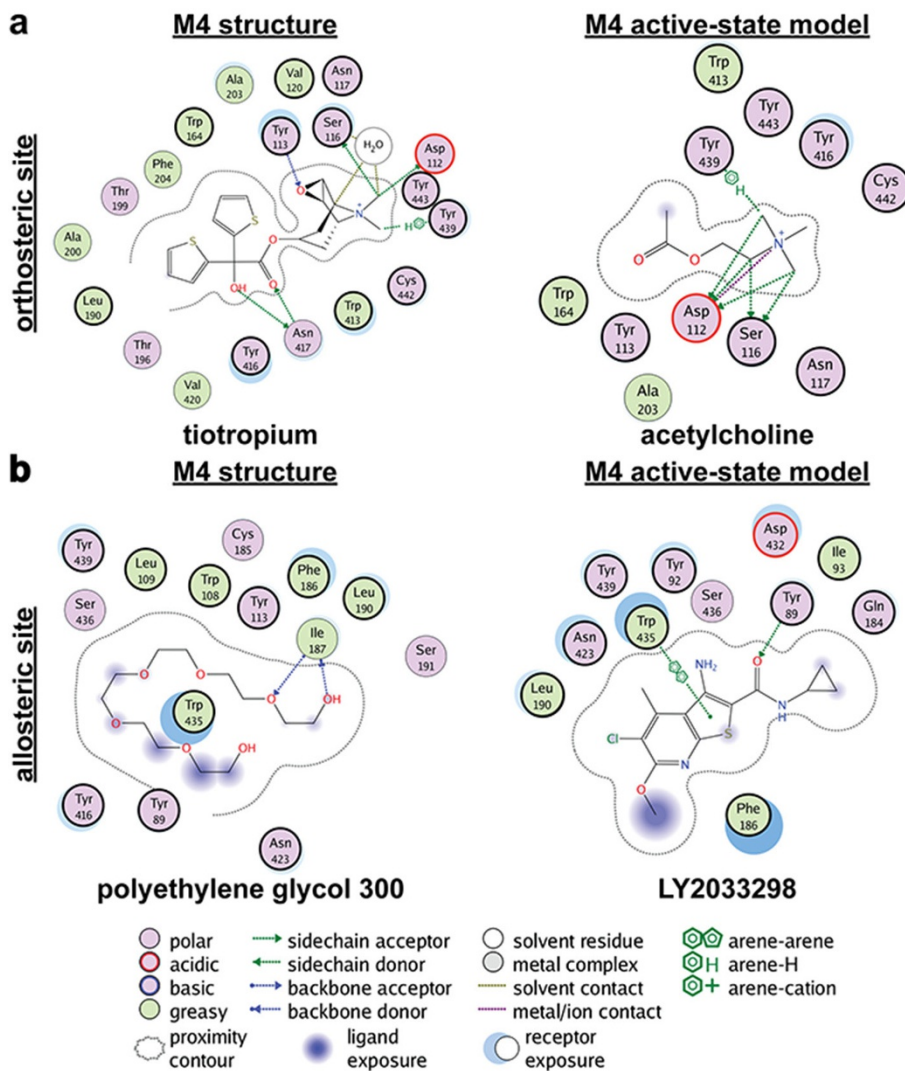

Extended Data Figure 4 | Induced fit docking of pirenzepine into the M1–M4 structures. The receptors shown are aligned and coloured as in Fig. 1. **a**, Superposition of the poses of pirenzepine from the IFD

experiments. **b**, Comparison of the pirenzepine poses for the M1 and M4 receptor with residues that contribute to the orthosteric site of the M1–M4 receptors (several residues omitted for clarity).

Extended Data Figure 5 | PEG 300 occupies the allosteric binding site of the inactive M4 receptor. **a**, The cross section of the solvent accessible surface area of the M4 receptor is coloured blue. Tiotropium and PEG 300 are shown as spheres with respective carbons coloured white and peach. The aromatic cage of covering tiotropium is highlighted in orange **b**, View from the extracellular side with residues that contact PEG 300 shown as spheres. **c**, Dissociation kinetics of [³H]NMS in the presence

of PEG 300. [³H]NMS was incubated with M4-mT4L membranes at 37 °C for 3 h, followed by addition of 10 μM atropine ± PEG 300 at the indicated concentrations and time points. Representative data from three experiments, performed in duplicate, fitted to a one-phase exponential decay are shown. **d**, PEG 300 has an apparent binding affinity for the NMS-occupied receptor of approximately 10 mM ($\log(\text{IC}_{50}) = -1.95 \pm 0.02$).

Extended Data Figure 6 | Ligand interaction diagrams for the M4 receptor. a, b, The molecular interactions between the (a) orthosteric and (b) allosteric binding sites are shown by the program

MOE⁶⁵ for the inactive (M4•tiotropium structure) and active states (M4•acetylcholine•LY2033298 model). Residues with a bold outline were selected in this study or others^{20,21} as single-point mutations.

Extended Data Figure 7 | Identification of key residues that govern LY2033298 affinity and binding cooperativity with ACh at the M4 receptor. Competition between a fixed concentration of [³H]QNB and increasing concentrations of ACh (black circles), LY2033298 (blue triangles), or LY2033298 in the presence of an IC₂₀ concentration of ACh (red squares) are shown. The curves drawn through the points

represent the best global fit of an extended ternary complex model. For data sets where the binding of [³H]QNB changed by less than 10% at 10⁻⁵ M LY2033298 relative to zero LY2033298, the value of α' was fixed to 1 (connecting line shown). Data points represent the mean \pm s.e.m. of at least three experiments performed in triplicate.

Extended Data Figure 8 | Comparison of cooperativity network residues between the inactive and active-states. a, b, Chemical structures of (a) the M4 ligands used in this study and (b) the M2 ligands from the active-state crystal structures (PDB accession number 4MQT and 4MQS). c–f, Mapping of the allosteric network onto the (c, d) inactive M4

structure (blue residues), M4 active-state model (orange residues) and (e, f) the inactive (yellow residues) and active-state M2 structures (magenta and green residues) with views from the (c, e) membrane or (d, f) extracellular surface. Ligands are coloured according to element: carbon, cyan; oxygen, red; nitrogen, blue; sulfur, yellow; chlorine, green.

Extended Data Figure 9 | LY2033298 binding to active-state M1 and M4 models. Comparison of active-state M1 (green) and M4 (orange) models bound to LY2033298 and acetylcholine, with acetylcholine and LY2033298 shown as sticks and coloured according to element: carbon, white; oxygen, red; nitrogen, blue; sulfur, yellow; chlorine, green. Several residues surrounding LY2033298 are shown as sticks and coloured according to receptor. M4-N423^{6.58} is predicted to undergo significant movement between the inactive and active states to form a hydrogen bond with the methoxy group of LY2033298. In the M1 receptor this residue is a serine (S388^{6.58}) and is unable to form a similar hydrogen bond. However, mutation of N423^{6.58} to alanine at the M4 receptor results in no loss of LY2033298 affinity, but does result in a sixfold loss in cooperativity between acetylcholine and LY2033298 (Supplementary Table 3). This is suggestive of selectivity being derived through cooperativity as a possible mechanism between the M1 and M4 receptors. Additional determinants for M1 and M4 selectivity could also arise through differences in residues on TMs 2 and 7, which contribute to (I93^{2.65}) or sit proximal to (D432^{7.32} and S436^{7.36}) the allosteric network.
