Received October 10, 2018; revised October 27, 2018; accepted November 7, 2018

**Abstract**—Co<sub>3</sub>O<sub>4</sub> modified TiO<sub>2</sub> nanotube arrays (TiO<sub>2</sub>–NTs) were successfully fabricated by electrodeposition and thermal oxidation process. The prepared samples were characterized by field emission scanning electron microscopy (FESEM), transmission electron microscopic (TEM), X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), and UV-visible diffuse reflectance spectroscopy. The photoelectrocatalytic properties of as-prepared samples were investigated under visible light and UV-vis light irradiation. Meanwhile, taking methyl orange aqueous solution as target substrate for photoelectrocatalytic degradation experiments, the degradation rate under UV-vis light irradiation and dark condition were evaluated. The prepared Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>–NTs exhibited much higher photoelectrochemical activity than TiO<sub>2</sub>–NTs under visible light irradiation and UV-vis light irradiation. The degradation rate of methyl orange on Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>–NTs electrode reaches 90.7% under applied potential of 1.3 V and UV-vis light irradiation for 10 h, which is only 53.4% on TiO<sub>2</sub>–NTs electrode. The improved performance could be attributed to the higher photo-generated carrier concentration and carrier mobility.

**Keywords:** TiO<sub>2</sub> nanotube arrays, Co<sub>3</sub>O<sub>4</sub> nanoparticles, photoelectrocatalysis, methyl orange degradation

## INTRODUCTION

Water pollution has always been a major concern among the environmental issues, most of the pollutants in water are stable in nature. The environmental laws and regulations become more stringent [1], and efficient degradation methods appeal to lots of researchers all over the world. Many reports [2–4] demonstrate that semiconductor heterojunction catalysts can effectively degrade organic pollutants under appropriate conditions. TiO<sub>2</sub> nanotube arrays as an *n*-type semiconductor attract tremendous attention because of their unique structure and excellent properties [5, 6], which is widely used in photodegradation [7], sensors [8], hydrogen generation [9], and dye sensitized solar cells [10, 11]. Nevertheless, the intrinsic band gap of TiO<sub>2</sub> (3.2 eV for anatase and 3.0 eV for rutile) limits its absorption in the ultraviolet part of solar spectrum [12]. The construction of a heterostructure by metal-oxide-

semiconductor doping on TiO<sub>2</sub> is an effective way to solve this issue [13].

Many metal oxides (such as Bi<sub>2</sub>O<sub>3</sub> [14], Co<sub>3</sub>O<sub>4</sub> [15], SnO<sub>2</sub> [16], WO<sub>3</sub> [17], and ZnO [18]) have been reported to couple with TiO<sub>2</sub> to form heterostructured photocatalysts with enhanced photocatalysis. Among them, Co<sub>3</sub>O<sub>4</sub> is one of the most intriguing *p*-type semiconductor materials with two band gaps of 1.5 and 2.2 eV [15]. Up to this day, cobalt oxide thin-film can be prepared by many methods, such as RF sputtering [19], chemical vapor deposition [20], spray pyrolysis [21], and electrodeposition techniques [22]. Numerous studies have proved that a *p*-*n* junction photocatalysts coupled with other semiconductors is an efficient way to enhance the photocatalytic activity of the Co<sub>3</sub>O<sub>4</sub> [23]. Cao et al. [24] introduced photochemical coating method to prepare Co<sub>3</sub>O<sub>4</sub>-modified TiO<sub>2</sub> nanorod arrays, which remarkably enhanced visible light photoelectrochemical response in comparison with the pure TiO<sub>2</sub>–NTs. Fan et al. [25] developed a photodeposition strategy to synthesize Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub> com-

<sup>1</sup> The text was submitted by the authors in English.

posites, which significantly enhanced performance for lithium-ion batteries. Wang et al. [26] prepared Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub> nanofibers heterostructure via a simple two-step process including electrospinning and hydrothermal process, and found that the prepared material exhibited a relatively high catalysis response to CO.

In this work, well ordered TiO<sub>2</sub> nanotube arrays was coupled with Co<sub>3</sub>O<sub>4</sub> nanoparticles via a simple electrodeposition and thermal oxidation process. The photoelectrocatalytic activity of the prepared Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs was evaluated for the degradation of methyl orange. It is aimed to provide a new route to synthesis Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs hybrid with excellent photoelectrocatalytic properties under visible light.

## EXPERIMENTAL

**Material synthesis.** TiO<sub>2</sub>-NTs was prepared on commercial pure titanium substrates (purity 99.95%) by potentiostatic anodization in 1 wt % hydrofluoric solution at 20 V for 20 min [27]. The as-prepared electrode was thoroughly washed by deionized water and then annealed at 450°C for 2 h with heating and cooling rates of 5°C/min in air.

Co<sub>3</sub>O<sub>4</sub> nanoparticles were loaded on TiO<sub>2</sub>-NTs via electrodeposition followed by thermal oxidation treatments. Electrodeposition was carried out in a solution composed of 0.05 M CoSO<sub>4</sub> and 1 M (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> at current density of -1 mA cm<sup>-2</sup>. Pt was used as auxiliary electrode. Thermal oxidation was performed at 450°C for 2 h in a quartz tube furnace.

**Characterization.** The morphology of the as-prepared samples was measured by field-emission scanning electron microscopy (FESEM, Hitachi S-4700) and transmission electron microscopic (TEM, FEI, TecnaiG2F30). X-ray diffraction (XRD) patterns of the TiO<sub>2</sub> nanotube were characterized on a PHILIPS Panalytical X'Pert PRO using CuK<sub>α</sub> radiation. X-ray photo electron spectroscopy (XPS) measurements were performed on a Kratos AXIS Ultra DLD Xray photoelectron spectrometer system with a AlK<sub>α</sub> X-ray source ( $h = 1486.6$  eV). Binding energy values were calibrated by the reference of contaminant carbon (C1s = 284.8 eV). UV-visible diffuse reflectance spectra were obtained on an UV-visible spectrophotometer (UV-2550, Shimadzu, Japan). BaSO<sub>4</sub> was used as a reflectance standard.

**Photoelectrochemical measurements.** The photoelectrochemical properties were investigated in a con-

ventional three-electrode system on CHI660C electrochemical workstation. The prepared sample with exposure area of 1 cm<sup>2</sup>, platinum sheet and saturated calomel electrode (SCE) were used as working electrode, counter electrode and reference electrode, respectively. 0.2 M Na<sub>2</sub>SO<sub>4</sub> aqueous solution was used as the electrolyte. A 300 W Xenon lamp (Au Light, CEL-TCX250) with a visible-light filter (>420 nm) was used as light source for the photoelectrochemical measurement.

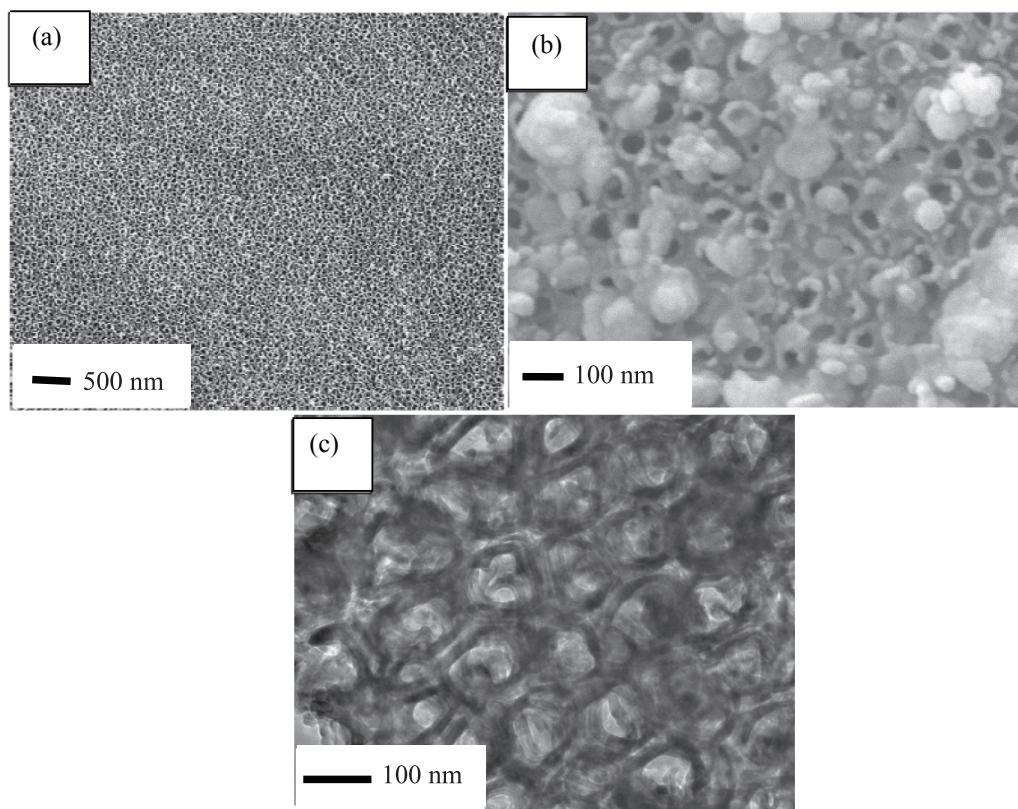

### Photoelectrocatalytic degradation experiments.

The photoelectrocatalytic degradation experiments were investigated by using 30 mL methyl orange with an initial concentration of 4 mg L<sup>-1</sup> as model pollutant in a homemade rectangular glass container (4 cm × 2 cm × 5 cm). One side of the container was quartz glass, so the UV light can get through. A 300W Xenon lamp (Au Light, CEL-TCX250) was positioned 10 cm away from the container and the light intensity reaching the surface of sample was about 18 mW cm<sup>-2</sup>. The photoelectrochemical degradation reactions were carried out at applied potential of 1.3 V under UV-vis light irradiation. The concentration of methyl orange was analyzed using UV-visible spectrophotometer at wavelength of 462.5 nm.

## RESULTS AND DISCUSSION

**Characterization of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs.** The morphologies of TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs were observed by SEM and TEM. Figure 1a is a typical SEM image of TiO<sub>2</sub>-NTs obtained by anodic oxidation, which reveals a regularly arranged tubular structure. Figure 1b shows the surface morphology of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs. It can be seen that most Co<sub>3</sub>O<sub>4</sub> was deposited into the pore space of TiO<sub>2</sub>-NTs successfully, only few spherical Co<sub>3</sub>O<sub>4</sub> nanoparticles was grown on the surface of TiO<sub>2</sub>-NTs. Figure 1c is the TEM image of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs, in which the TiO<sub>2</sub> nanotubes are clearly visible and the deposits are located in both the inner side of nanotubes and the gap between nanotubes.

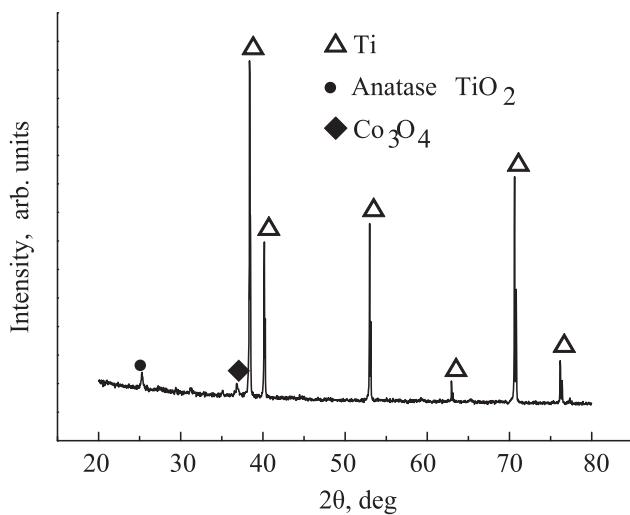

Figure 2 shows the XRD pattern of the prepared Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs. The diffraction peaks of Ti are clearly seen because Ti is a substrate with high crystallinity and the thick of layer is only several hundred nanometers. The peak emerging at 25.28° is attributed to the (101) reflection of anatase phase TiO<sub>2</sub> (JCPSD, no. 71-1166). And the peak at 36.82° corresponds to the (311) of cubic phase Co<sub>3</sub>O<sub>4</sub> (JCPSD, no. 73-1701). No other diffraction

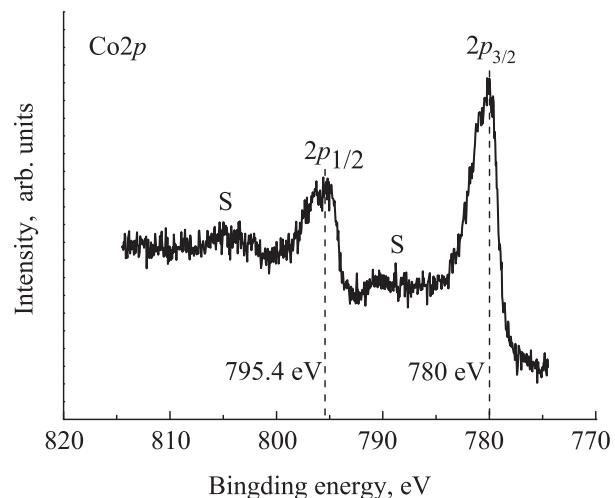

**Fig. 1.** SEM images of (a) TiO<sub>2</sub>-NTs, (b) Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs, and (c) TEM image of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs.

peaks could be detected. XRD analysis indicates that heat treatment enables a complete transformation of the electrodeposited cobalt to Co<sub>3</sub>O<sub>4</sub>, after which Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs nanostructured electrode was obtained.

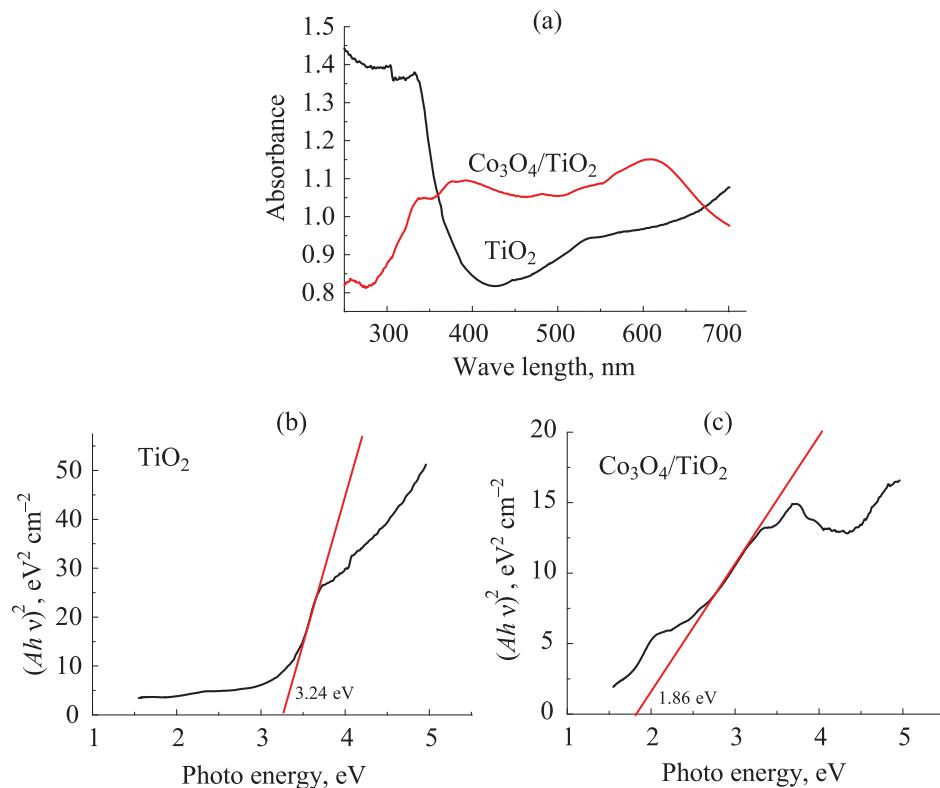

X-ray photoelectron spectroscopy was measured to further determine the valence state of Co in the prepared sample. Figure 3 represents the XPS spectrum of Co<sub>2p</sub>, from which we can find that the main Co<sub>2p</sub>

**Fig. 2.** XRD pattern of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs.

**Fig. 3.** XPS spectra of the Co<sub>2p</sub> binding energy region of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs.

**Fig. 4.** (Color online) (a) UV-vis diffuse reflection spectra of TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs, (b) and (c) plot analysis of optical band gap of TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs, respectively

photoelectron peaks are located at 780 and 795.4 eV with two shake-up satellite peaks at about 788.7 and 804.8 eV. The emerged peaks indicate that the Co is in the form of trivalence, corresponding well with Co<sub>3</sub>O<sub>4</sub> [28, 29], i.e. the synthesized sample is Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs.

**UV-vis diffuse reflection spectra.** Figure 4 shows the UV-vis diffuse reflectance spectra of TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs. It is apparent that Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs exhibits an enhanced absorption in all visible and part of the ultraviolet region compared with TiO<sub>2</sub>-NTs. However, TiO<sub>2</sub>-NTs showed a higher absorption in most ultraviolet region.

The energy band gap ( $E_g$ ) can be estimated by the Tauc equation [30]:

$$\alpha h\nu = C(h\nu - E_g)^n, \quad (1)$$

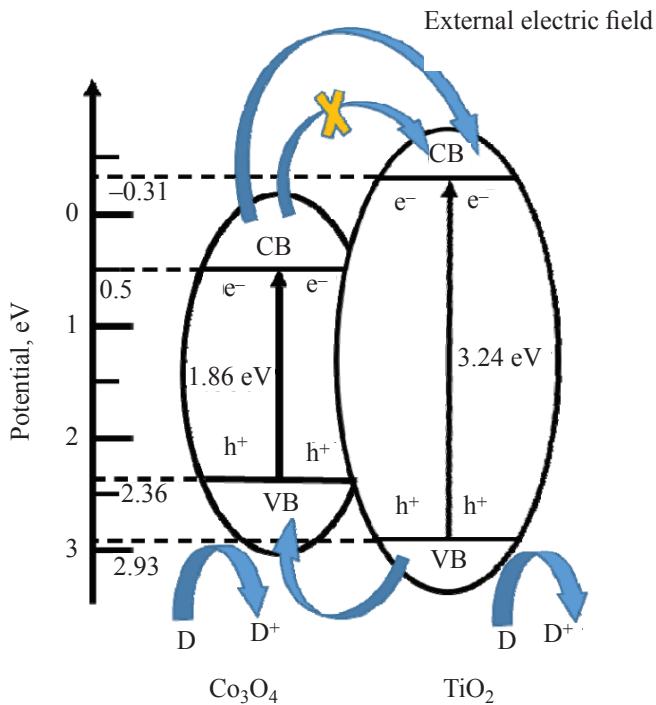

where  $h\nu$  is the photon energy,  $C$  is the constant,  $\alpha$  is the absorption coefficient,  $n = 2$  for an indirect bandgap semiconductor and  $n = 1/2$  for a direct bandgap semiconductor. The  $E_g$  is calculated by a linear fit to the experimental  $(\alpha h\nu)^2$  vs.  $h\nu$  plot. The intersection point of the tangent and horizontal ordinate is the  $E_g$ . It can

be seen from Fig. 4 that the  $E_g$  of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs is 1.86 eV, whereas the  $E_g$  of TiO<sub>2</sub>-NTs is 3.24 eV. This result also indicates that the TiO<sub>2</sub> in this case has an anatase crystal, which is basically consistent with the XRD results. The valence band edge position of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs heterostructure can be estimated by a simple approach. The valence band potential at the point of zero charge was calculated by the following equation [31]:

$$E_{VB} = X - E^e + 0.5E_g, \quad (2)$$

where  $E_{VB}$  is the valence band edge potential,  $X$  is the geometric mean of the absolute electronegativity of the constituent atoms,  $E^e$  is the energy of free electrons on the hydrogen scale (about 4.5 eV), and the conduction band potential ( $E_{CB}$ ) can be determined by  $E_{CB} = E_{VB} - E_g$ . The  $X$  values for TiO<sub>2</sub> and Co<sub>3</sub>O<sub>4</sub> are 5.81 and 5.93 eV, the  $E_{VB}$  of TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub> are calculated to be 2.93 and 2.36 eV, respectively. Therefore, the  $E_{CB}$  of TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub> are estimated to be -0.31 and 0.50 eV.

A schematic diagram for the photo-generated charge separation of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs heterostructure is established, as shown in Fig. 5. When the *p-n*

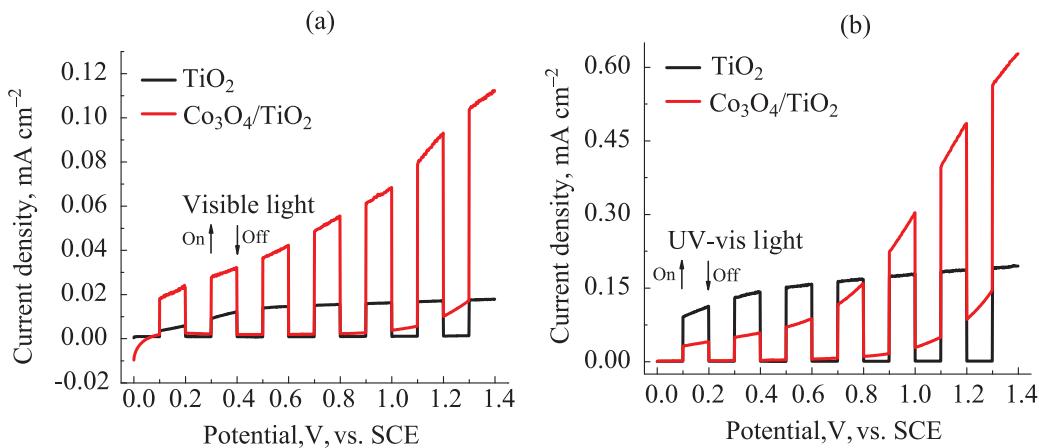

**Fig. 5.** (Color online) Schematic diagram for the photo-generated charge separation of  $\text{Co}_3\text{O}_4/\text{TiO}_2$ -NTs.

junction is formed, the free electrons of the *n*-type semiconductor ( $\text{TiO}_2$ ) are combined with the holes of *p*-type semiconductor ( $\text{Co}_3\text{O}_4$ ). At this time, the *p*-type semiconductor is negatively charged, and the *n*-type semiconductor is positively charged, thereby forming an internal electric field from the *n*-type  $\text{TiO}_2$  to *p*-type  $\text{Co}_3\text{O}_4$ . According to the band edge position, photo-generated holes on the valence band (VB) of *n*-type  $\text{TiO}_2$  can transfer to *p*-type  $\text{Co}_3\text{O}_4$  easily [32], while the photogenerated electrons on the conduction band (CB) can not transfer from  $\text{Co}_3\text{O}_4$  to  $\text{TiO}_2$  without the aid of external electric field.

**Photoelectrochemical performance.** Figure 6 shows the photocurrent densities of  $\text{TiO}_2$ -NTs and  $\text{Co}_3\text{O}_4/\text{TiO}_2$ -NTs measured under visible light illumination and UV-vis light illumination in 0.2 M  $\text{Na}_2\text{SO}_4$  solution. Under visible light irradiation, the photoresponse on  $\text{TiO}_2$ -NTs is very weak because  $\text{TiO}_2$ -NTs can hardly absorb visible light due to its wide intrinsic band gap. While for the case of  $\text{Co}_3\text{O}_4/\text{TiO}_2$ -NTs, there is a significant improvement in the photoelectrochemical performance, which is evidenced by the enhanced photocurrent. As Fig. 5 demonstrates, the  $\text{Co}_3\text{O}_4$  nanoparticles has narrow bandgap close to the energy of visible light, so it can be excited by sunlight. At the

same time, the  $\text{Co}_3\text{O}_4$  and  $\text{TiO}_2$ -NTs form a *p-n* junction, which benefits the separation of photon-generated carriers and then leads to a higher photocurrent density. It is also found that with the increase in applied potential, the photocurrent of  $\text{Co}_3\text{O}_4/\text{TiO}_2$ -NTs increased rapidly, while the photocurrent of  $\text{TiO}_2$ -NTs had no evident changes. For  $\text{TiO}_2$ -NTs, carrier mobility reached a maximum value under a low potential and the concentration of photo-generated carrier were lower.  $\text{Co}_3\text{O}_4/\text{TiO}_2$ -NTs were in a different situation, not only for its higher photo-generated carrier concentration, but also for its increasing carrier mobility.

The responses of the  $\text{TiO}_2$ -NTs and  $\text{Co}_3\text{O}_4/\text{TiO}_2$ -NTs under UV-vis light irradiation are shown in Fig. 5b. Different from visible light irradiation,  $\text{TiO}_2$ -NTs exhibit an obvious absorption in ultraviolet region. When the applied potential is lower than 0.8 V,  $\text{Co}_3\text{O}_4/\text{TiO}_2$ -NTs hybrid does not show comparative advantage compared with  $\text{TiO}_2$ -NTs. However, when the applied potential is greater than 0.8 V, the existence of  $\text{Co}_3\text{O}_4$  nanoparticles significantly enhanced its photoelectrochemical performance. As previously stated, carrier mobility reached a maximum value under a low potential for  $\text{TiO}_2$ -NTs, so its photocurrent has no evident changes with the increase in applied potential. It is found that the doping of

**Fig. 6.** (Color online) Photocurrent vs. potential curves for TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs in 0.2 M Na<sub>2</sub>SO<sub>4</sub> solution under (a) visible light illumination and (b) UV-vis light illumination.

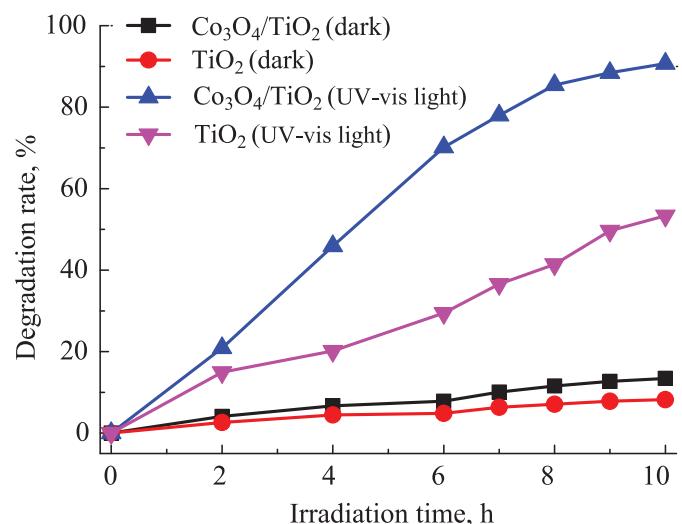

Co<sub>3</sub>O<sub>4</sub> nanoparticles into TiO<sub>2</sub>-NTs causes the photocurrent decay to some extent at low potential, which may be owing to the lower carrier mobility in Co<sub>3</sub>O<sub>4</sub> nanoparticles and the photo-generated carriers in Co<sub>3</sub>O<sub>4</sub> nanoparticles are easy to recombination in this condition. However, carrier mobility increases significantly with the increase of the potential for the Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs sample, that's why the photocurrent density of Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs reached 0.56 mA cm<sup>-2</sup> when potential is 1.3 V, approximately three times higher than TiO<sub>2</sub>-NTs.

**Photoelectrocatalytic degradation methyl orange.** Photoelectrocatalytic degradation methyl orange was conducted to evaluate the performance of the prepared Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs. Figure 7 displays the degradation curves of methyl orange on different samples under UV-vis light illumination with applied potential of 1.3 V. For comparison, the degradation experiment under dark condition is also conducted. It is found that both TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs show a significantly enhancement in degradation rate under UV-vis light illumination. Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs displays a superior photoelectrocatalytic activity, and 90.7% of methyl orange molecules are degraded under UV-vis light irradiation for 10 h. In contrast, only 53.4% of methyl orange molecules are degraded by TiO<sub>2</sub>-NTs.

## CONCLUSIONS

In summary, Co<sub>3</sub>O<sub>4</sub> modified TiO<sub>2</sub> nanotube arrays (TiO<sub>2</sub>-NTs) were successfully fabricated by electrodeposition and thermal oxidation process. The photoelectro-

chemical performance of TiO<sub>2</sub>-NTs and Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs were measured under visible light illumination and UV-vis light illumination. The existence of Co<sub>3</sub>O<sub>4</sub> nanoparticles significantly enhances the visible light response. When the applied potential is lower than 0.8 V, Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs hybrid does not show comparative advantage compared with TiO<sub>2</sub>-NTs. While at potential greater than 0.8 V, the doping of Co<sub>3</sub>O<sub>4</sub> nanoparticles significantly enhances its photoelectrochemical performance under UV-vis light irradiation. The degradation rate of methyl orange on Co<sub>3</sub>O<sub>4</sub>/TiO<sub>2</sub>-NTs electrode

**Fig. 7.** (Color online) Photoelectrochemical degradation curves of methyl orange on samples under UV-vis light illumination and dark condition with 1.3 V potential.

reaches 90.7% under applied potential of 1.3 V and UV-vis light irradiation for 10 h, which is only 53.4% on TiO<sub>2</sub>-NTs electrode. The improved performance could be attributed to the higher photo-generated carrier concentration and carrier mobility.
